# ON IRRELEVANCE AND ALGORITHMIC EQUALITY IN PREDICATIVE TYPE THEORY* 

ANDREAS ABEL ${ }^{a}$ AND GABRIEL SCHERER ${ }^{b}$<br>${ }^{a}$ Department of Computer Science, Ludwig-Maximilians-University Munich e-mail address: andreas.abel@ifi.lmu.de<br>${ }^{b}$ Gallium team, INRIA Paris-Rocquencourt e-mail address: gabriel.scherer@gmail.com

#### Abstract

Dependently typed programs contain an excessive amount of static terms which are necessary to please the type checker but irrelevant for computation. To separate static and dynamic code, several static analyses and type systems have been put forward. We consider Pfenning's type theory with irrelevant quantification which is compatible with a type-based notion of equality that respects $\eta$-laws. We extend Pfenning's theory to universes and large eliminations and develop its meta-theory. Subject reduction, normalization and consistency are obtained by a Kripke model over the typed equality judgement. Finally, a type-directed equality algorithm is described whose completeness is proven by a second Kripke model.

## 1. Introduction and Related Work

Dependently typed programming languages such as Agda BDN09, Coq [INR10, and Epigram MM04 allow the programmer to express in one language programs, their types, rich invariants, and even proofs of these invariants. Besides code executed at run-time, dependently typed programs contain much code needed only to please the type checker, which is at the same time the verifier of the proofs woven into the program.

Program extraction takes type-checked terms and discards parts that are irrelevant for execution. Augustsson's dependently typed functional language Cayenne Aug99 erases types using a universe-based analysis. Coq's extraction procedure has been designed by Paulin-Mohring and Werner PMW93] and Letouzey Let02] and discards not only types but also proofs. The erasure rests on Coq's universe-based separation between propositional (Prop) and computational parts (Set/Type). The rigid Prop/Set distinction has the drawback of code duplication: A structure which is sometimes used statically and sometimes dynamically needs to be coded twice, once in Prop and once in Set.

An alternative to the fixed Prop/Set-distinction is to let the usage context decide whether a term is a proof or a program. Besides whole-program analyses such as data

[^0]flow, some type-based analyses have been put forward. One of them is Pfenning's modal type theory of Intensionality, Extensionality, and Proof Irrelevance [Pfe01], later pursued by Reed [Ree03], which introduces functions with irrelevant arguments that play the role of proofs 1 Not only can these arguments be erased during extraction, they can also be disregarded in type conversion tests during type checking. This relieves the user of unnecessary proof burden (proving that two proofs are equal). Furthermore, proofs can not only be discarded during program extraction but directly after type checking, since they will never be looked at again during type checking subsequent definitions.

In principle, we have to distinguish "post mortem" program extraction, let us call it external erasure, and proof disposal during type checking, let us call it internal erasure. External erasure deals with closed expressions, programs, whereas internal erasure deals with open expressions that can have free variables. Such free variables might be assumed proofs of (possibly false) equations and block type casts, or (possibly false) proofs of wellfoundedness and prevent recursive functions from unfolding indefinitely. For type checking to not go wrong or loop, those proofs can only be externally erased, thus, the Prop/Set distinction is not for internal erasure. In Pfenning's type theory, proofs can never block computations even in open expressions (other than computations on proofs), thus, internal erasure is sound.

Miquel's Implicit Calculus of Constructions (ICC) Miq01a goes further than Pfenning and considers also parametric arguments as irrelevant. These are arguments which are irrelevant for function execution but relevant during type conversion checking. Such arguments may only be erased in function application but not in the associated type instantiation. Barras and Bernardo BB08 and Mishra-Linger and Sheard MLS08 have built decidable type systems on top of ICC, but both have not fully integrated inductive types and types defined by recursion (large eliminations). Barras and Bernardo, as Miquel, have inductive types only in the form of their impredicative encodings, Mishra-Linger [ML08 gives introduction and elimination principles for inductive types by example, but does not show normalization or consistency.

While Pfenning's type theory uses typed equality, ICC and its successors interpret typed expressions as untyped $\lambda$-terms up to untyped equality. In our experience, the implicit quantification of ICC, which allows irrelevant function arguments to appear unrestricted in the codomain type of the function, is incompatible with type-directed equality. Examples are given in Section [2.3. Therefore, we have chosen to scale Pfenning's notion of proof irrelevance up to inductive types, and integrated it into Agda.

In this article, we start with the "extensionality and proof irrelevance" fragment of Pfenning's type theory in Reed's version Ree02, Ree03]. We extend it by a hierarchy of predicative universes, yielding Irrelevant Intensional Type Theory IITT (Sec. [2). After specifying a type-directed equality algorithm (Sec. 3), we construct a Kripke model for IITT (Sec. (4). It allows us to prove normalization, subject reduction, and consistency, in one go (Sec. 5). A second Kripke logical relation yields correctness of algorithmic equality and decidability of IITT (Sec. [6). Our models are ready for data types, large eliminations, types with extensionality principles, and internal erasure (Sec. 7).

[^1]Contribution and Related Work. We consider the design of our meta-theoretic argument as technical novelty, although it heavily relies on previous works to which we owe our inspiration. Allen [All87] describes a logical relation for Martin-Löf type theory with a countable universe hierarchy. The seminal work of Coquand Coq91 describes an untyped equality check for the Logical Framework and justifies it by a logical relation for dependent types that establishes subject reduction, normalization, completeness of algorithmic equality, and injectivity of function types in one go. However, his approach cannot be easily extended to a typed algorithmic equality, due to problems with transitivity.

Goguen introduces Typed Operational Semantics Gog94 to construct a Kripke logical relation that simultaneously proves normalization, subject reduction, and confluence for a variant of the Calculus of Inductive Constructions. From his results one can derive an equality check based on reduction to normal form. Goguen also shows how to derive syntactic properties, such as closure of typing and equality under substitution, by a Kripke-logical relation Gog00.

Harper and Pfenning [HP05] popularize a type-directed equality check for the Logical Framework that scales to extensionality for unit types. They prove completeness of algorithmic equality by a Kripke model on simple types which are obtained by erasure from the dependent types. Erasure is necessary since algorithmic equality cannot be shown transitive before it is proven sound; yet soundness hinges on subject reduction which rests on function type injectivity which in turn is obtained from completeness of algorithmic equality - a vicious cycle. While erasure breaks the cycle, it also prevents types to be defined by recursion on values (so-called large eliminations), a common feature of proof assistants like Agda, Coq, and Epigram.

Normalization by evaluation (NbE) has been successfully used to obtain a type-directed equality check based on evaluation in the context of dependent types with large eliminations ACD07. In previous work ACD08, the first author applied NbE to justify a variant of Harper and Pfenning's algorithmic equality without erasure. However, the meta-theoretic argument is long-winded, and there is an essential gap in the proof of transitivity of the Kripke logical relation.

In this work, we explore a novel approach to justify type-directed algorithmic equality for dependent types with predicative universes. First, we show its soundness by a Kripke model built on top of definitional equality. The Kripke logical relation yields normalization, subject reduction, and type constructor injectivity, which also imply logical consistency of IITT. Further, it proves syntactic properties such as closure under substitution, following Goguen's lead Gog00. The semantic proof of such syntactic properties relieves us from the deep lemma dependencies and abundant traps of syntactic meta-theory of dependent types HP05, AC07. Soundness of algorithmic equality entails transitivity (which is the stumbling stone), paving the way to show completeness of algorithmic equality by a second Kripke logical relation, much in the spirit of Coquand Coq91 and Harper and Pfenning HP05.

This article is a revised and extended version of paper Irrelevance in Type Theory with a Heterogeneous Equality Judgement presented at the conference FoSSaCS 2011 [Abe11]. Unfortunately, the conference version has inherited the above-mentioned gap [ACD08] in the proof of transitivity of the Kripke logical relation. This is fixed in the present article by an auxiliary Kripke model (Section (4). Further, we have dropped the heterogeneous approach to equality in favor of a standard homogeneous one. Heterogeneous equality is not necessary for the style of irrelevance we are embracing here.

## 2. Irrelevant Intensional Type Theory

In this section, we present Irrelevant Intensional Type Theory IITT which features two of Pfenning's function spaces [Pfe01, the ordinary "extensional" $(x: U) \rightarrow T$ and the proof irrelevant $(x \div U) \rightarrow T$. The main idea is that the argument of a $(x \div U) \rightarrow T$ function is counted as a proof and can neither be returned nor eliminated on, it can only be passed as argument to another proof irrelevant function or data constructor. Technically, this is realized by annotating variables as relevant, $x: U$, or irrelevant, $x \div U$, in the typing context, to confine occurrences of irrelevant variables to irrelevant arguments.

Expression and context syntax. We distinguish between relevant ( $t^{:} u$ or simply $t u$ ) and irrelevant application $(t \div u)$. Accordingly, we have relevant $(\lambda x: U . T)$ and irrelevant abstraction $(\lambda x \div U . T)$. Our choice of typed abstraction is not fundamental; a bidirectional type-checking algorithm Coq96 can reconstruct type and relevance annotations at abstractions and applications.

$$
\begin{array}{lll}
\text { Var } \ni x, y, X, Y & & \\
\text { Sort } \ni s & ::=\operatorname{Set}_{k}(k \in \mathbb{N}) & \\
\text { Ann } \ni \star & ::=\div \mid: & \\
\text { Exp } \ni t, u, T, U & ::=s \mid(x \star U) \xrightarrow{s, s^{\prime}} T & \\
& & \text { annotation: irrelevant, relevant } \\
& |x| \lambda x \star U \cdot t \mid t^{\star} u & \\
\text { Expele } & \text { lambda-calculus } \\
\text { Cxt } \ni \Gamma, \Delta & ::=\diamond \mid \Gamma . x \star T & \\
\text { empty, (ir)relevant extension }
\end{array}
$$

Expressions are considered modulo $\alpha$-equality, we write $t \equiv t^{\prime}$ when we want to stress that $t$ and $t^{\prime}$ identical (up to $\alpha$ ). Similarly, we consider variables bound in a context to be distinct, and when opening a term binder we will implicitly use $\alpha$-conversion to add a fresh variable in the context.

For technical reasons, namely, to prove transitivity (Lemma 4.3) of the Kripke logical relation in Section 4, we explicitly annotate function types $(x \star U) \xrightarrow{s, s^{\prime}} T$ with the sorts $s$ of domain $U$ and $s^{\prime}$ of codomain $T$. We may omit the annotation if it is inessential or determined by the context of discourse. In case $T$ does not mention $x$, we may write $U \rightarrow T$ for $(x: U) \rightarrow T$.

Sorts. IITT is a pure type system (PTS) with infinite hierarchy of predicative universes Set $_{0}$ : Set $_{1}$ : .... The universes are not cumulative. We have the PTS axioms Axiom = $\left\{\left(\operatorname{Set}_{i}, \operatorname{Set}_{i+1}\right) \mid i \in \mathbb{N}\right\}$ and the rules Rule $=\left\{\left(\operatorname{Set}_{i}, \operatorname{Set}_{j}, \operatorname{Set}_{m a x}(i, j)\right) \mid i, j \in \mathbb{N}\right\}$. As is customary, we will write the side condition $\left(s, s^{\prime}\right) \in$ Axiom just as $\left(s, s^{\prime}\right)$ and likewise $\left(s_{1}, s_{2}, s_{3}\right) \in$ Rule just as $\left(s_{1}, s_{2}, s_{3}\right)$. IITT is a full and functional PTS, which means that for all $s_{1}, s_{2}$ there is exactly one $s_{3}$ such that $\left(s_{1}, s_{2}, s_{3}\right)$. There is no subtyping, so that types-and thus, sorts-are unique up to equality. A proof of sort unicity might relieve us from the sort annotation in function types, however, we obtain sort discrimination too late in our technical development (Lemma 5.10).

Substitutions. Substitutions $\sigma$ are maps from variables to expressions. We require that the domain $\operatorname{dom}(\sigma)=\{x \mid \sigma(x) \neq x\}$ is finite. We write id for the identity substitution and $[u / x]$ for the singleton substitution $\sigma$ such that $\sigma(x):=u$ and $\sigma(y):=y$ for $y \neq x$. Substitution extension $(\sigma, u / x)$ is formally defined as $\sigma \uplus[u / x]$. Capture avoiding parallel substitution of $\sigma$ in $t$ is written as juxtaposition $t \sigma$.

Contexts. Contexts $\Gamma$ feature two kinds of bindings, relevant $(x: U)$ and irrelevant $(x \div U)$ ones. The intuition, implemented by the typing rules below, is that only relevant variables are in scope in an expression. Resurrection $\Gamma^{\mp}$ turns all irrelevant bindings $(x \div T)$ into the corresponding relevant ones $(x: T)$ [Pe01]. It is the tool to make irrelevant variables, also called proof variables, available in proofs. The generalization $\Gamma^{\star}$ shall mean $\Gamma^{\div}$if $\star=\div$, and just $\Gamma$ otherwise. We write $\Gamma . \Delta$ for the concatenation of $\Gamma$ and $\Delta$; herein, we suppose $\operatorname{dom}(\Gamma) \cap \operatorname{dom}(\Delta)=\emptyset$.

Primitive judgements of IITT. The following three judgements are mutually inductively defined by the rules given below and in Figure $\mathbb{1}$.

$$
\begin{array}{ll}
\vdash \Gamma & \text { Context } \Gamma \text { is well-formed. } \\
\Gamma \vdash t: T & \text { In context } \Gamma, \text { expression } t \text { has type } T . \\
\Gamma \vdash t=t^{\prime}: T & \text { In context } \Gamma, t \text { and } t^{\prime} \text { are equal expressions of type } T .
\end{array}
$$

Derived judgements. To simplify notation, we introduce the following four abbreviations:

$$
\begin{array}{lll}
\Gamma \vdash t \div T & \text { iff } & \Gamma^{\div} \vdash t: T \\
\Gamma \vdash t=t^{\prime} \div T & \text { iff } & \Gamma \vdash t \div T \text { and } \Gamma \vdash t^{\prime} \div T \\
\Gamma \vdash T & \text { iff } & \Gamma \vdash T: s \text { for some } s \\
\Gamma \vdash T=T^{\prime} & \text { iff } & \Gamma \vdash T=T
\end{array}
$$

$\Gamma \vdash t \star T$ may mean $\Gamma \vdash t: T$ or $\Gamma \vdash t \div T$, depending on the value of placeholder $\star$; same for $\Gamma \vdash t=t^{\prime} \star T$. We sometimes write $\Gamma \vdash t, t^{\prime} \star T$ to abbreviate the conjunction of $\Gamma \vdash t \star T$ and $\Gamma \vdash t^{\prime} \star T$. The notation $\Gamma \vdash T, T^{\prime}$ is to be understood similarly.
2.1. Rules. Our rules for well-typed terms $\Gamma \vdash t: T$ extend Reed's rules Ree02 to PTS style. There are only 6 rules; we shall introduce them one-by-one.

Variable rule. Only relevant variables can be extracted from the context.

$$
\frac{\vdash \Gamma \quad(x: U) \in \Gamma}{\Gamma \vdash x: U}
$$

There is no variable rule for irrelevant bindings $(x \div U) \in \Gamma$, in particular, the judgement $x \div U \vdash x: U$ is not derivable. This essentially forbids proofs to appear in relevant positions.

Abstraction rule. Relevant and irrelevant functions are introduced analogously.

$$
\frac{\Gamma . x \star U \vdash t: T \quad \Gamma \vdash(x \star U) \xrightarrow{s, s^{\prime}} T}{\Gamma \vdash \lambda x \star U \cdot t:(x \star U) \xrightarrow{s, s^{\prime}} T}
$$

To check a relevant function $\lambda x: U$.t, we introduce a relevant binding $x: U$ into the context and continue checking the function body $t$. In case of an irrelevant function $\lambda x \div U$.t, we proceed with an irrelevant binding $x \div U$. This means that an irrelevant function cannot computationally depend on its argument - it is essentially a constant function. In particular, $\lambda x \div U . x$ is never well-typed.

As a side condition, we also need to check that the introduced function type $(x \star U) \xrightarrow{s, s^{\prime}} T$ is well-sorted; the rule is given below.

Application rule.

$$
\frac{\Gamma \vdash t:(x \star U) \rightarrow T \quad \Gamma \vdash u \star U}{\Gamma \vdash t^{\star} u: T[u / x]}
$$

This rule uses our overloaded notations for bindings $\star$, that can be specialized into two different instances for relevant and irrelevant applications.

For relevant functions, we get the ordinary dependently-typed application rule:

$$
\frac{\Gamma \vdash t:(x: U) \rightarrow T \quad \Gamma \vdash u: U}{\Gamma \vdash t u: T[u / x]}
$$

When applying an irrelevant function, we resurrect the context before checking the function argument.

$$
\frac{\Gamma \vdash t:(x \div U) \rightarrow T \quad \Gamma^{\doteqdot} \vdash u: U}{\Gamma \vdash t \div u: T[u / x]}
$$

This means that irrelevant variables become relevant and can be used in $u$. The intuition is that the application $t \div u$ does not computationally depend on $u$, thus, $u$ may refer to any variable, even the "forbidden ones". One may think of $u$ as a proof which may refer to both ordinary and proof variables.

For example, let $\Gamma=f:(y \div U) \rightarrow U$. Then the irrelevant $\eta$-expansion $\lambda x \div U . f \div x$ is well-typed in $\Gamma$, with the following derivation:

$$
\frac{\overline{\Gamma . x \div U \vdash f:(y \div U) \rightarrow U} \overline{\Gamma \cdot x: U \vdash x: U}}{\frac{\Gamma \cdot x \div U \vdash f \div x: U}{\Gamma \vdash \lambda x \div U \cdot f^{\circ} x:(x \div U) \rightarrow U}}
$$

Observe how the status of $x$ changes for irrelevant to relevant when we check the argument of $f$.

Sorting rules. These are the "Axioms" and the "Rules" of PTSs to form types.

$$
\frac{\vdash \Gamma}{\Gamma \vdash s: s^{\prime}}\left(s, s^{\prime}\right) \quad \frac{\Gamma \vdash U: s_{1} \quad \Gamma \cdot x \star U \vdash T: s_{2}}{\Gamma \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T: s_{3}}\left(s_{1}, s_{2}, s_{3}\right)
$$

The rule for irrelevant function type formation follows Reed Ree02.

$$
\frac{\Gamma \vdash U: s_{1} \quad \Gamma . x \div U \vdash T: s_{2}}{\Gamma \vdash(x \div U) \xrightarrow{s_{1}, s_{2}} T: s_{3}}\left(s_{1}, s_{2}, s_{3}\right)
$$

It states that the codomain of an irrelevant function cannot depend relevantly on the function argument. This fact is crucial for the construction of our semantics in Section 4 Note that it rules out polymorphism in the sense of Barras and Bernado's Implicit Calculus of Constructions ICC* BB08] and Mishra-Linger and Sheard's Erasure Pure Type Systems EPTS MLS08; the type $\left(X \div \operatorname{Set}_{0}\right) \rightarrow(x: X) \rightarrow X$ is ill-formed in IITT, but not in ICC* or EPTS. In EPTS, there is the following rule:

$$
\frac{\Gamma \vdash U: s_{1} \quad \Gamma \cdot x: U \vdash T: s_{2}}{\Gamma \vdash(x \div U) \xrightarrow{s_{1}, s_{2}} T: s_{3}}\left(s_{1}, s_{2}, s_{3}\right)
$$

It allows the codomain $T$ of an irrelevant function to arbitrarily depend on the function argument $x$. This is fine in an erasure semantics, but incompatible with our typed semantics in the presence of large eliminations; we will detail the issues in examples 2.3 and 2.8.

Another variant is Pfenning's rule for irrelevant function type formation [fe01.

$$
\frac{\Gamma \vdash U \div s_{1} \quad \Gamma . x \div U \vdash T: s_{2}}{\Gamma \vdash(x \div U) \xrightarrow{s_{1}, s_{2}} T: s_{3}}\left(s_{1}, s_{2}, s_{3}\right)
$$

It allows the domain of an irrelevant function to make use of irrelevant variables in scope. It does not give polymorphism, e. g., $\left(X \div \operatorname{Set}_{0}\right) \rightarrow(x: X) \rightarrow X$ is still ill-formed. However, $\left(X \div \operatorname{Set}_{0}\right) \rightarrow(x \div X) \rightarrow X$ would be well-formed. It is unclear how the equality rule for irrelevant function types would look like - it is not given by Pfenning Pfe01. The rule

$$
\frac{\Gamma \vdash U=U^{\prime} \div s_{1} \quad \Gamma \cdot x \div U \vdash T=T^{\prime}: s_{2}}{\Gamma \vdash(x \div U) \stackrel{s_{1}, s_{2}}{\longrightarrow} T=\left(x \div U^{\prime}\right) \stackrel{s_{1}, s_{2}}{\longrightarrow} T^{\prime}: s_{3}}\left(s_{1}, s_{2}, s_{3}\right)
$$

would mean that any two irrelevant function types are equal as long as their codomains are equal - their domains are irrelevant. This is not compatible with our typed semantics and seems a bit problematic in general:2

Type conversion rule. We have typed conversion, thus, strictly speaking, IITT is not a PTS, but a Pure Type System with Judgemental Equality Ada06].

$$
\frac{\Gamma \vdash t: T \quad \Gamma \vdash T=T^{\prime}}{\Gamma^{\prime} \vdash t: T^{\prime}}
$$

Equality. Figure 1 recapitulates the typing rules and lists the rules to derive context wellformedness $\vdash \Gamma$ and equality $\Gamma \vdash t=t^{\prime}: T$. Equality is the least congruence over the $\beta$ and $\eta$-axioms. Since equality is typed we can extend IITT to include an extensional unit type (Section 7). Let us inspect the congruence rule for application:

$$
\frac{\Gamma \vdash t=t^{\prime}:(x \star U) \rightarrow T \quad \Gamma \vdash u=u^{\prime} \star U}{\Gamma \vdash t^{\star} u=t^{\prime \star} u^{\prime}: T[u / x]}
$$

In case of relevant functions ( $\star=:$ ) we obtain the usual dependently-typed application rule of equality. Otherwise, we get:

$$
\frac{\Gamma \vdash t=t^{\prime}:(x \div U) \rightarrow T \quad \Gamma^{\div} \vdash u: U}{} \quad \Gamma^{\div} \vdash u^{\prime}: U ~
$$

Note that the arguments $u$ and $u^{\prime}$ to the irrelevant functions need to be well-typed but not related to each other. This makes precise the intuition that $t$ and $t^{\prime}$ are constant functions.
2.2. Simple properties of IITT. In the following, we prove two basic invariants of derivable IITT-judgements: The context is always well-formed, and judgements remain derivable under well-formed context extensions (weakening).

Lemma 2.1 (Context well-formedness).
(1) If $\vdash \Gamma . x: U . \Gamma^{\prime}$ then $\Gamma \vdash U$.
(2) If $\Gamma \vdash t: T$ or $\Gamma \vdash t=t^{\prime}: T$ then $\vdash \Gamma$.

Proof. By a simple induction on the derivations.

[^2]
## Context well-formedness.

$$
\overline{\vdash \diamond} \quad \frac{\vdash \Gamma \quad \Gamma \vdash T}{\vdash \Gamma \cdot x \star T}
$$

Typing.
$\Gamma \vdash t: T$

$$
\begin{aligned}
& \frac{\vdash \Gamma}{\Gamma \vdash s: s^{\prime}}\left(s, s^{\prime}\right) \quad \frac{\Gamma \vdash U: s_{1} \quad \Gamma \cdot x \star U \vdash T: s_{2}}{\Gamma \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T: s_{3}}\left(s_{1}, s_{2}, s_{3}\right) \\
& \frac{\vdash \Gamma \quad(x: U) \in \Gamma}{\Gamma \vdash x: U} \quad \frac{\Gamma \cdot x \star U \vdash t: T \quad \Gamma \vdash(x \star U) \xrightarrow[\rightarrow]{s, s^{\prime}} T}{\Gamma \vdash \lambda x \star U \cdot t:(x \star U) \xrightarrow{s, s^{\prime}} T} \\
& \frac{\Gamma \vdash t:(x \star U) \rightarrow T}{\Gamma \vdash t^{\star} u: T[u / x]} \quad \Gamma \vdash u \star U \\
& \frac{\Gamma \vdash t: T \quad \Gamma \vdash T=T^{\prime}}{\Gamma^{\prime} \vdash t: T^{\prime}}
\end{aligned}
$$

Equality.
$\Gamma \vdash t=t^{\prime}: T$
Computation ( $\beta$ ) and extensionality $(\eta$ ).

$$
\frac{\Gamma \cdot x \star U \vdash t: T \quad \Gamma \vdash u \star U}{\Gamma \vdash(\lambda x \star U \cdot t)^{\star} u=t[u / x]: T[u / x]} \quad \frac{\Gamma \vdash t:(x \star U) \xrightarrow{s, s^{\prime}} T}{\Gamma \vdash t=\lambda x \star U \cdot t \star x:(x \star U) \xrightarrow{s, s^{\prime}} T}
$$

Equivalence rules.

$$
\frac{\Gamma \vdash t: T}{\Gamma \vdash t=t: T} \quad \frac{\Gamma \vdash t=t^{\prime}: T}{\Gamma \vdash t^{\prime}=t: T} \quad \frac{\Gamma \vdash t_{1}=t_{2}: T}{\Gamma \vdash t_{1}=t_{3}: T}
$$

Compatibility rules.

$$
\begin{gathered}
\frac{\Gamma \vdash U=U^{\prime}: s_{1} \quad \Gamma \cdot x \star U \vdash T=T^{\prime}: s_{2}}{\Gamma \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T=\left(x \star U^{\prime}\right) \stackrel{s_{1}, s_{2}}{\rightarrow} T^{\prime}: s_{3}}\left(s_{1}, s_{2}, s_{3}\right) \\
\frac{\Gamma \vdash U=U^{\prime}: s_{1} \quad \Gamma \cdot x \star U \vdash T: s_{2} \quad \Gamma \cdot x \star U \vdash t=t^{\prime}: T}{\Gamma \vdash \lambda x \star U \cdot t=\lambda x \star U^{\prime} \cdot t^{\prime}:(x \star U) \xrightarrow{s_{1}, s_{2}} T} \\
\frac{\Gamma \vdash t=t^{\prime}:(x \star U) \rightarrow T \quad \Gamma \vdash u=u^{\prime} \star U}{\Gamma \vdash t^{\star} u=t^{\prime} \star u^{\prime}: T[u / x]}
\end{gathered}
$$

Conversion rule.

$$
\frac{\Gamma \vdash t=t^{\prime}: T \quad \Gamma \vdash T=T^{\prime}}{\Gamma \vdash t=t^{\prime}: T^{\prime}}
$$

Figure 1: Rules of IITT

It should be noted that we only prove the most basic well-formedness statements here. One would expect that $\Gamma \vdash t: T$ or $\Gamma \vdash t=t^{\prime}: T$ also implies $\Gamma \vdash T$, or that $\Gamma \vdash t=t^{\prime}: T$ implies $\Gamma \vdash t: T$. This is true-and we will refer to these implications as syntactic validity - but this cannot be proven without treatment of substitution, due to the typing rule for application, which requires substitution in the type, and due to the equality rule for a $\beta$-redex, which uses substitution in both term and type. Therefore, syntactic validity is delayed until Section 4 (Corollary 4.17), where substitution will be handled by semantic, rather than syntactic, methods.

Weakening. We can weaken a context $\Gamma$ by adding bindings or making irrelevant bindings relevant. Formally, we have an order on binding annotations, which is the order induced by $: \leq \div$, and we define weakening by monotonic extension.

A well-formed context $\vdash \Delta$ extends a well-formed context $\vdash \Gamma$, written $\Delta \leq \Gamma$, if and only if:

$$
\forall x \in \operatorname{dom}(\Gamma), \quad\left(x \star_{1} U\right) \in \Gamma \Longrightarrow\left(x \star_{2} U\right) \in \Delta \text { with } \star_{1} \leq \star_{2} .
$$

Note that this allows to insert new bindings or relax existing ones at any position in $\Gamma$, not just at the end.
Lemma 2.2 (Weakening). Let $\Delta \leq \Gamma$.
(1) If $\vdash \Gamma . \Gamma^{\prime}$ and $\operatorname{dom}(\Delta) \cap \operatorname{dom}\left(\Gamma^{\prime}\right)=\emptyset$ then $\vdash \Delta . \Gamma^{\prime}$.
(2) If $\Gamma \vdash t: T$ then $\Delta \vdash t: T$.
(3) If $\Gamma \vdash t=t^{\prime}: T^{\prime}$ then $\Delta \vdash t=t^{\prime}: T$.

Proof. Simultaneously by induction on the derivation. Let us look at some cases:
Case

$$
\frac{\vdash \Gamma}{\Gamma \vdash s=s: s^{\prime}}\left(s, s^{\prime}\right)
$$

By assumption $\vdash \Delta$, thus $\Delta \vdash s=s: s^{\prime}$.
Case

$$
\frac{(x: U) \in \Gamma \quad \vdash \Gamma}{\Gamma \vdash x=x: U}
$$

Since $\Delta \leq \Gamma$ we have $(x: U) \in \Delta$, thus $\Delta \vdash x=x: U$.
Case

$$
\frac{\Gamma \vdash U=U^{\prime}: s_{1} \quad \Gamma \cdot x \star U \vdash T: s_{2} \quad \Gamma \cdot x \star U \vdash t=t^{\prime}: T}{\Gamma \vdash \lambda x \star U \cdot t=\lambda x \star U^{\prime} \cdot t^{\prime}:(x \star U) \xrightarrow{s_{1}, s_{2}} T}
$$

W.l.o.g., $x \notin \operatorname{dom}(\Delta)$. By (11) and definition of context weakening, $\Delta \leq \Gamma$ implies $\Delta . x \star U \leq \Gamma . x \star U$, so all premises can be appropriately weakened by induction hypothesis.

### 2.3. Examples.

Example 2.3 (Relevance of types). 3 We can extend IITT by a unit type 1 with extensionality principle.

$$
\frac{\vdash \Gamma}{\Gamma \vdash 1: \operatorname{Set}_{i}} \quad \frac{\vdash \Gamma}{\Gamma \vdash(): 1} \quad \frac{\Gamma \vdash t: 1 \quad \Gamma \vdash t^{\prime}: 1}{\Gamma \vdash t=t^{\prime}: 1}
$$

[^3]Typed equality allows us to equate all inhabitants of the unit type. As a consequence, the Church numerals over the unit type all coincide, e. g.,

$$
\begin{aligned}
\Gamma & \vdash \lambda f: 1 \rightarrow 1 . \lambda x: 1 . x \\
& =\lambda f: 1 \rightarrow 1 . \lambda x: 1 . f x:(1 \rightarrow 1) \rightarrow 1 \rightarrow 1
\end{aligned}
$$

In systems with untyped equality, like ICC* and EPTS, these terms erase to untyped Church-numerals $\lambda f \lambda x . x$ and $\lambda f \lambda x . f x$ and are necessarily distinguished.

If we trade the unit type for Bool or any other type with more than one inhabitant, the two terms become different in IITT. This means that in IITT, types are relevant, and we need to reject irrelevant quantification over types like in $\left(X \div \operatorname{Set}_{0}\right) \rightarrow(X \rightarrow X) \rightarrow X \rightarrow X$. In IITT, the polymorphic types of Church numerals are $\left(X: \operatorname{Set}_{i}\right) \rightarrow(X \rightarrow X) \rightarrow X \rightarrow X$.

Example 2.4 ( $\Sigma$-types). IITT can be readily extended by weak $\Sigma$-types.

$$
\begin{gathered}
\frac{\Gamma \vdash U: s_{1} \quad \Gamma \cdot x \star U \vdash T: s_{2}}{\Gamma \vdash(x \star U) \times T: s_{3}}\left(s_{1}, s_{2}, s_{3}\right) \\
\frac{\Gamma \vdash u \star U \quad \Gamma \vdash t: T[u / x] \quad \Gamma \vdash(x \star U) \times T}{\Gamma \vdash(u, t):(x \star U) \times T} \\
\frac{\Gamma \vdash u \star U}{} \quad \frac{\Gamma \vdash p:(x \star U) \times T \quad \Gamma \cdot x \star U \cdot y: T \vdash v: V}{\Gamma \vdash \operatorname{let}(x, y)=p \text { in } v: V} \\
\\
\\
\Gamma \vdash(\operatorname{let}(x, y)=(u, t) \text { in } v)=v[u / x][t / y]: V
\end{gathered}
$$

Additional laws for equality could be considered, like commuting conversions, or the identity (let $(x, y)=p$ in $(x, y))=p$. The relevant form $(x: U) \times T$ admits a strong version with projections fst and snd and full extensionality $p=($ fst $p$, snd $p):(x: U) \times T$. However, strong irrelevant $\Sigma$-types $(x \div U) \times T$ are problematic because of the first projection:

$$
\frac{\Gamma \vdash p:(x \div U) \times T}{\Gamma \vdash \text { fst } p \div U}
$$

With our definition of $\Gamma \vdash u \div U$ as $\Gamma^{\doteqdot} \vdash u: U$, this rule is misbehaved: it allows us get hold of an irrelevant value in a relevant context. We could define a closed function $\pi_{1}:(x \div U) \times 1 \rightarrow U$, and composing it with $(-,()):(x \div U) \rightarrow(x \div U) \times 1$ would give us an identity function of type $(x \div U) \rightarrow U$ which magically makes irrelevant things relevant and IITT inconsistent. In this article, we will not further consider strong $\Sigma$-types with irrelevant components; we leave the in-depth investigation to future work.

Example 2.5 (Squash type). The squash type $\|T\|$ was first introduced in the context of NuPRL [CAB ${ }^{+86]}$; it contains exactly one inhabitant iff $T$ is inhabited. Semantically, one obtains $\|T\|$ from $T$ by equating all of $T$ 's inhabitants. In IITT, we can define $\|T\|$ as internalization of the irrelevance modality, as already suggested by Pfenning [Pfe01. The
first alternative is via the weak irrelevant $\Sigma$-type.

$$
\begin{aligned}
& \|-\|: \quad \operatorname{Set}_{i} \rightarrow \operatorname{Set}_{i} \\
& \|T\|:=(-\div T) \times 1 \\
& \text { [-] : } \quad(x \div T) \rightarrow\|T\| \\
& {[x]:=(x,())} \\
& \operatorname{sqelim}\left(T: \operatorname{Set}_{i}\right)\left(P:\|T\| \rightarrow \operatorname{Set}_{j}\right)(f:(x \div T) \rightarrow P[x])(t:\|T\|) \\
& \text { : } \quad P t \\
& :=\text { let }\left(x,,_{-}\right)=t \text { in } f \div x
\end{aligned}
$$

It is not hard to see that $\|-\|$ is a monad. All canonical inhabitants of $\|T\|$ are definitionally equal:

$$
\frac{\Gamma \vdash t, t^{\prime} \div T}{\Gamma \vdash[t]=\left[t^{\prime}\right]:\|T\|}
$$

This is easily shown by expanding the definition of []] and using the congruence rule for pairs with an irrelevant first component.

However, we cannot show that all inhabitants of $\|T\|$ are definitionally equal, because of the missing extensionality principles for weak $\Sigma$. Thus, the second alternative is to add the squash type to IITT via the rules:

$$
\begin{gathered}
\frac{\Gamma \vdash T: \operatorname{Set}_{i}}{\Gamma \vdash\|T\|: \operatorname{Set}_{i}} \quad \frac{\Gamma \vdash t \div T}{\Gamma \vdash[t]:\|T\|} \quad \frac{\Gamma \vdash t:\|T\| \quad \Gamma \cdot x \div T \vdash v: V}{\Gamma \vdash \operatorname{let}[x]=t \text { in } v: V} \\
\frac{\Gamma \vdash t, t^{\prime}:\|T\|}{\Gamma \vdash t=t^{\prime}:\|T\|} \quad \frac{\Gamma \vdash t \div T \quad \Gamma \cdot x \div T \vdash v: V}{\Gamma \vdash(\operatorname{let}[x]=[t] \text { in } v)=v[t / x]: V}
\end{gathered}
$$

Our model (Section(4) is ready to interpret these rules, as well as normalization-by-evaluation inspired models ACP11.
Example 2.6 (Subset type). The subset type $\{x: U \mid T\}$ is definable from $\Sigma$ and squash as $(x: U) \times\|T\|$.

To discuss the next example, we consider a further extension of IITT by Leibniz equality and natural numbers:

$$
\begin{array}{lll}
a \equiv b & : \operatorname{Set}_{i} & \text { for } A: \operatorname{Set}_{i} \text { and } a, b: A \\
\text { refl } & : a \equiv a & \text { for } A: \operatorname{Set}_{i} \text { and } a: A \\
\text { Nat } & : \operatorname{Set}_{i} \\
0,1, \ldots & \\
+\operatorname{Nat}^{*} & : \text { Nat } \rightarrow \text { Nat } \rightarrow \text { Nat. }
\end{array}
$$

Example 2.7 (Composite). $\left\{\begin{array}{l}\text { Let the set of composite numbers }\{4,6,8,9,10,12,14,15, \ldots\}\end{array}\right.$ be numbers that are the product of two natural numbers $\geq 2$.

$$
\text { Composite }=\{n: \text { Nat } \mid(k: \text { Nat }) \times(l: \text { Nat }) \times(n \equiv(k+2) *(l+2))\}
$$

Most composite numbers have several factorizations, and thanks to irrelevance the specific composition is ignored when handling composite numbers. For instance, 12 as product of 3 and 4 is not distinguished from the 12 as product of 2 and 6 .

$$
(12,[(1,(2, \text { refl }))])=(12,[(0,(4, \text { refl }))]): \text { Composite. }
$$

[^4]Example 2.8 (Large eliminations). 5 The ICC BB08 or EPTS MLS08 irrelevant function type $(x \div A) \rightarrow B$ allows $x$ to appear relevantly in $B$. This extra power raises some issues with large eliminations. Consider

$$
\begin{aligned}
\mathrm{T}: & \text { Bool } \rightarrow \text { Set }_{0} \\
\mathrm{~T} \text { true }= & \text { Bool } \rightarrow \text { Bool } \\
\mathrm{T} \text { false }= & \text { Bool } \\
t \quad= & \lambda F:(b \div \text { Bool }) \rightarrow(\mathrm{T} b \rightarrow \mathrm{~T} b) \rightarrow \text { Set }_{0} . \\
& \lambda g:(F \div \text { false }(\lambda x: \text { Bool. } x)) \rightarrow \text { Bool. } \\
& \lambda a: F^{\circ} \text { true }(\lambda x: \text { Bool } \rightarrow \text { Bool. } \lambda y: \text { Bool. } x y) . g a .
\end{aligned}
$$

The term $t$ is well-typed in $\mathrm{ICC}^{*}+\mathrm{T}$ because the domain type of $g$ and the type of $a$ are $\beta \eta$-equal after erasure $(-)^{*}$ of type annotations and irrelevant arguments:

$$
\left.\begin{array}{rl}
(F \doteqdot \text { false }(\lambda x: \text { Bool. } x))^{*} & =F(\lambda x x) \\
& ={ }_{\beta \eta} F(\lambda x \lambda y . x y)
\end{array}\right)\left(F^{\doteqdot} \text { true }(\lambda x: \text { Bool } \rightarrow \text { Bool. } \lambda y: \text { Bool. } x y)\right)^{*} .
$$

While a Curry view supports this, it is questionable whether identity functions at different types should be viewed as one. It is unclear how a type-directed equality algorithm (see Sec. (3) should proceed here; it needs to recognize that $x$ : Bool is equal to $\lambda y$ : Bool. $x y$ : Bool $\rightarrow$ Bool. This situation is amplified by a unit type 1 with extensional equality. When we change T true to 1 and the type of $a$ to $F^{\dagger}$ true $(\lambda x: 1$. ()) then $t$ should still type-check, because $\lambda x$. () is the identity function on 1 . However, $\eta$-equality for 1 cannot be checked without types, and a type-directed algorithm would end up checking (successfully) $x$ : Bool for equality with (): 1. This algorithmic equality cannot be transitive, because then any two booleans would be equal.

Summarizing, we may conclude that the type of $F$ bears trouble and needs to be rejected. IITT does this because it forbids the irrelevant $b$ in relevant positions such as T $b$; ICC* lacks T altogether. Extensions of ICC* should at least make sure that $b$ is never eliminated, such as in T $b$. Technically, T would have to be put in a separate class of recursive functions, those that actually compute with their argument. We leave the interaction of the three different function types to future research.

## 3. Algorithmic Equality

The algorithm for checking equality in IITT is inspired by Harper and Pfenning HP05. Like theirs, it is type-directed, but we are using the full dependent type and not an erasure to simple types (which would anyway not work due to large eliminations). We give the algorithm in form of judgements and rules in direct correspondence to a functional program.

Algorithmic equality is meant to be used as part of a type checking algorithm. It is the algorithmic counterpart of the definitional conversion rule; in particular, it will only be called on terms that are already know to be well-typed - in fact, types that are well-sorted. We rely on this precondition in the algorithmic formulation.

Algorithmic equality consists of three interleaved judgements. A type equality test checks equality between two types, by inspecting their weak head normal forms. Terms found inside dependent types are reduced and the resulting neutral terms are compared by structural equality. The head variable of such neutrals provides type information that is

[^5]then used to check the (non-normal) arguments using type-directed equality, by reasoning on the (normalized) type structure to perform $\eta$-expansions on product types. After enough expansions, a base type is reached, where structural equality is called again, or a sort, at which we use type equality.

Informally, the interleaved reductions are the algorithmic counterparts of the $\beta$-equality axiom, the type and structural equalities account for the compatibility rules, and typedirected equality corresponds to the $\eta$-equality axiom. The remaining equivalence rules are emergent global properties of the algorithm.

Weak head reduction. Weak head normal forms (whnfs) are given by the following grammar:

$$
\begin{array}{llll}
\text { Whnf } \ni a, b, f, A, B, F & ::=s\left|(x \star U) \xrightarrow{s, s^{\prime}} T\right| \lambda x \star U . t \mid n & \text { whnf } \\
\text { Wne } \ni n, N & :==x \mid n^{\star} u & \text { neutral whnf }
\end{array}
$$

Weak head evaluation $t \searrow a$ and active application $f @^{\star} u \searrow a$ are functional relations given by the following rules.

$$
\frac{t \searrow f \quad f @^{\star} u \searrow a}{t^{\star} u \searrow a} \quad \overline{a \searrow a} \quad \frac{t[u / x] \searrow a}{(\lambda x \star U \cdot t) @^{\star} u \searrow a} \quad \overline{n @^{\star} u \searrow n^{\star} u}
$$

Instead of writing the propositions $t \searrow a$ and $P[a]$ we will sometimes simply write $P[\downarrow t]$. Similarly, we might write $P\left[f @^{\star} u\right]$ instead of $f @^{\star} u \searrow a$ and $P[a]$. In rules, it is understood that the evaluation judgement is always an extra premise, never an extra conclusion.

Algorithmic equality is given as type equality, structural equality, and type-directed equality, which are mutually recursive. The equality algorithm is only invoked on wellformed expressions of the correct type.

Type equality. Type equality $\Delta \vdash A \Longleftrightarrow A^{\prime}$, for weak head normal forms, and $\Delta \vdash T \Longleftrightarrow$ $T^{\prime}$, for arbitrary well-formed types, checks that two given types are equal in their respective contexts.

$$
\begin{gathered}
\frac{\Delta \vdash \downarrow T}{\Delta \vdash T} \Longleftrightarrow \stackrel{\Longleftrightarrow T^{\prime}}{\Longleftrightarrow} \quad \frac{\Delta \vdash N \longleftrightarrow T^{\prime}}{\Delta \vdash N \Longleftrightarrow N^{\prime}: T} \\
\frac{\Delta \vdash s}{\Delta \vdash s} \quad \frac{\Delta \vdash U \Longleftrightarrow U^{\prime}}{\Delta \vdash(x \star U) \xrightarrow{s, s^{\prime}} T \Longleftrightarrow\left(x \star U^{\prime}\right) \stackrel{s, s^{\prime}}{\rightarrow} T^{\prime}}
\end{gathered}
$$

Note that when invoking structural equality on neutral types $N$ and $N^{\prime}$, we do not care which type $T$ is returned, since we know by well-formedness that $N$ and $N^{\prime}$ must have the same sort.

Structural equality. Structural equality $\Delta \vdash n \longleftrightarrow n^{\prime}: A$ and $\Delta \vdash n \longleftrightarrow n^{\prime}: T$ checks the neutral expressions $n$ and $n^{\prime}$ for equality and at the same time infers their type, which is returned as output.

$$
\begin{aligned}
& \frac{\Delta \vdash n \longleftrightarrow n^{\prime}: T}{\Delta \vdash n \longleftrightarrow n^{\prime}: \downarrow T} \quad \frac{(x: T) \in \Delta}{\Delta \vdash x \longleftrightarrow x: T} \\
& \frac{\Delta \vdash n \longleftrightarrow n^{\prime}:(x: U) \rightarrow T \quad \Delta \vdash u \Longleftrightarrow u^{\prime}: U}{\Delta \vdash n u \overleftrightarrow{\longleftrightarrow} n^{\prime} u^{\prime}: T[u / x]} \quad \frac{\Delta \vdash n \longleftrightarrow n^{\prime}:(x \div U) \rightarrow T}{\Delta \vdash n \div u \longleftrightarrow n^{\prime} \div u^{\prime}: T[u / x]}
\end{aligned}
$$

Type-directed equality. Type-directed equality $\Delta \vdash t \Longleftrightarrow t^{\prime}: A$ and $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$ checks terms $t$ and $t^{\prime}$ for equality and proceeds by the structure of the supplied type, to account for $\eta$.

$$
\begin{gathered}
\frac{\Delta \vdash t \Longleftrightarrow t^{\prime}: \downarrow T}{\Delta \vdash t \Longleftrightarrow t^{\prime}: T} \quad \frac{\Delta \cdot x \star U \vdash t^{\star} x \Longleftrightarrow t^{\star} x: T}{\Delta \vdash t \Longleftrightarrow t^{\prime}:(x \star U) \rightarrow T} \\
\frac{\Delta \vdash T \Longleftrightarrow T^{\prime}}{\Delta \vdash T \Longleftrightarrow T^{\prime}: s} \quad \frac{\Delta \vdash \downarrow t \Longleftrightarrow \downarrow t^{\prime}: T}{\Delta \vdash t \Longleftrightarrow t^{\prime}: N}
\end{gathered}
$$

Note that in the but-last rule we do not check that the inferred type $T$ of $\downarrow t$ equals the ascribed type $N$. Since algorithmic equality is only invoked for well-typed $t$, we know that this must always be the case. Skipping this test is a conceptually important improvement over Harper and Pfenning [HP05].

Due to dependent typing, it is not obvious that algorithmic equality is symmetric and transitive. For instance, consider symmetry in case of application: We have to show that $\Delta \vdash n^{\prime} u^{\prime} \longleftrightarrow n u: T[u / x]$, but using the induction hypothesis we obtain this equality only at type $T\left[u^{\prime} / x\right]$. To conclude, we need to convert types, which is only valid if we know that $u$ and $u^{\prime}$ are actually equal. Thus, we need soundness of algorithmic equality to show its transitivity. Soundness w.r.t. declarative equality requires subject reduction, which is not trivial, due to its dependency on function type injectivity. In the next section (4), we construct by a Kripke logical relation which gives us subject reduction and soundness of algorithmic equality (Section 5), and, finally, symmetry and transitivity of algorithmic equality.

A simple fact about algorithmic equality is that the inferred types are unique up to syntactic equality (where we consider $\alpha$-convertible expressions as identical). Also, they only depend on the left hand side neutral term $n$.
Lemma 3.1 (Uniqueness of inferred types).
(1) If $\Delta \vdash n \longleftrightarrow n_{1}: A_{1}$ and $\Delta \vdash n \longleftrightarrow n_{2}: A_{2}$ then $A_{1} \equiv A_{2}$.
(2) If $\Delta \vdash n \longleftrightarrow n_{1}: T_{1}$ and $\Delta \vdash n \longleftrightarrow n_{2}: T_{2}$ then $T_{1} \equiv T_{2}$.

Extending structural equality to irrelevance, we let

$$
\frac{\Delta^{\div} \vdash n \longleftrightarrow n: A \quad \Delta^{\div} \vdash n^{\prime} \longleftrightarrow n^{\prime}: A}{\Delta \vdash n \longleftrightarrow n^{\prime} \div A}
$$

and analogously for $\Delta \vdash n \stackrel{\longleftrightarrow}{\longleftrightarrow} n^{\prime} \div T$.

## 4. A Kripke Logical Relation for Soundness

In this section, we construct a Kripke logical relation in the spirit of Goguen Gog00 and Vanderwaart and Crary VC02 that proves weak head normalization, function type injectivity, and subject reduction plus syntactical properties like substitution in judgements and syntactical validity. As an important consequence, we obtain soundness of algorithmic equality w.r.t. definitional equality. This allows us to establish that algorithmic equality on well-typed terms is a partial equivalence relation.
4.1. An Induction Measure. Following Goguen Gog94 and previous work ACD08, we first define a semantic universe hierarchy $U_{i}$ whose sole purpose is to provide a measure for defining a logical relation and proving some of its properties. The limit $U_{\omega}$ corresponds to the proof-theoretic strength or ordinal of IITT.

We denote sets of expressions by $\mathcal{A}, \mathcal{B}$ and functions from expressions to sets of expressions by $\mathcal{F}$. Let $\widehat{\mathcal{A}}=\{t \mid \downarrow t \in \mathcal{A}\}$ denote the closure of $\mathcal{A}$ by weak head expansion. The dependent function space is defined as $\Pi \mathcal{A} \mathcal{F}=\{f \in$ Whnf $\mid \forall u \in \widehat{\mathcal{A}} . f @ u \in \mathcal{F}(u)\}$.

By recursion on $i \in \mathbb{N}$ we define inductively sets $\mathrm{U}_{i} \subseteq$ Whnf $\times \mathcal{P}$ (Whnf) as follows ACD08, Sec. 5.1]:

$$
\begin{gathered}
\overline{(N, \mathrm{Wne}) \in \mathrm{U}_{i}} \quad \overline{\left(\operatorname{Set}_{j},\left|\mathrm{U}_{j}\right|\right) \in \mathrm{U}_{i}}\left(\operatorname{Set}_{j}, \operatorname{Set}_{i}\right) \in \text { Axiom } \\
\frac{(U, \mathcal{A}) \in \widehat{\mathrm{U}}_{i} \quad \forall u \in \widehat{\mathcal{A}} .(T[u / x], \mathcal{F}(u)) \in \widehat{\mathrm{U}}_{j}}{((x \star U) \rightarrow T, \Pi \mathcal{A} \mathcal{F}) \in \mathrm{U}_{k}}\left(\operatorname{Set}_{i}, \operatorname{Set}_{j}, \operatorname{Set}_{k}\right) \in \text { Rule }
\end{gathered}
$$

Herein, $\widehat{\mathrm{U}}_{i}=\left\{(T, \mathcal{A}) \mid(\downarrow T, \mathcal{A}) \in \mathrm{U}_{i}\right\}$ and $\left|\mathrm{U}_{j}\right|=\left\{A \mid(A, \mathcal{A}) \in \mathrm{U}_{j}\right.$ for some $\left.\mathcal{A}\right\}$. Only interested in computational strength, we treat relevant and irrelevant function spaces alike at the level of predicates $\mathcal{A}$, irrelevance is anyhow not observable, only by relations as given later.

The induction measure $A \in \operatorname{Set}_{i}$ shall now mean the minimum height of a derivation of $(A, \mathcal{A}) \in \mathrm{U}_{i}$ for some $\mathcal{A}$. Note that due to universe stratification, $A \in \operatorname{Set}_{i}$ is smaller than $\operatorname{Set}_{i} \in \operatorname{Set}_{j}$.
4.2. A Kripke Logical Relation. Let $\Delta \vdash t:=: t^{\prime} \star T$ stand for the conjunction of the propositions

- $\Delta \vdash t \star T$ and $\Delta \vdash t^{\prime} \star T$, and
- $\Delta \vdash t=t^{\prime} \star T$.

By induction on $A \in s$ we define two Kripke relations

$$
\begin{gathered}
\Delta \vdash A\left(S A^{\prime}: s\right. \\
\Delta \vdash a(S) a^{\prime}: A .
\end{gathered}
$$

together with their respective closures $\widehat{\widehat{S}}$ and the generalization to $\star$. For better readability, the clauses are given in rule form meaning that the conclusion is defined as the conjunction of the premises. $\forall$ and $\Longrightarrow$ are meta-level quantification and implication, respectively.

$$
\begin{aligned}
& \frac{\Delta \vdash N:=: N^{\prime}: s}{\Delta \vdash N(\subseteq) N^{\prime}: s} \quad \frac{\Delta \vdash n:=: n^{\prime}: N}{\Delta \vdash n(5) n^{\prime}: N} \quad \frac{\vdash \Delta}{\Delta \vdash s(5) s: s^{\prime}}\left(s, s^{\prime}\right) \\
& \Delta \vdash U \widehat{\widehat{S}} U^{\prime}: s_{1} \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\text { © }} u^{\prime} \star U \Longrightarrow \Gamma \vdash T[u / x] \widehat{\text { © }} T^{\prime}\left[u^{\prime} / x\right]: s_{2} \\
& \frac{\Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T:=:\left(x \star U^{\prime}\right) \xrightarrow{s_{1}, s_{2}} T^{\prime}: s_{3}}{\Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T(S)\left(x \star U^{\prime}\right) \xrightarrow{s_{1}, s_{2}} T^{\prime}: s_{3}}\left(s_{1}, s_{2}, s_{3}\right) \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\mathrm{~S}} u^{\prime} \star U \Longrightarrow \Gamma \vdash f^{\star} u \widehat{\widehat{S}} f^{\prime \star} u^{\prime}: T[u / x] \\
& \Delta \vdash f:=: f^{\prime}:(x \star U) \xrightarrow{s, s^{\prime}} T \\
& \Delta \vdash f(S) f^{\prime}:(x \star U) \xrightarrow{s, s^{\prime}} T
\end{aligned}
$$

$$
\begin{aligned}
& T \searrow A \quad \Delta \vdash T=A \\
& t \searrow a \quad \Delta \vdash t=a: A \quad \Delta \vdash t^{\prime}=a^{\prime}: A \quad t^{\prime} \searrow a^{\prime} \\
& \Delta \vdash a \text { (S } a^{\prime}: A \\
& \Delta \vdash t:=: t^{\prime}: T \\
& \Delta \vdash t \widehat{\text { © }} t^{\prime}: T
\end{aligned}
$$

It is immediate that the logical relation contains only well-typed and definitionally equal terms. We will demonstrate that it is also closed under weakening and conversion, symmetric and transitive.
Lemma 4.1 (Weakening).
(1) If $\Delta \vdash a$ © $a^{\prime}: A$ and $\Gamma \leq \Delta$ then there exists a derivation of $\Gamma \vdash a$ (S) $a^{\prime}: A$ with the same height.
(2) Analogously for $\Delta \vdash t \widehat{(\mathbb{S}} t^{\prime}: T$.

Proof. By induction on $A \in s$ and $T \in s$, resp.
Lemma 4.2 (Type conversion).
(1) If $\Gamma \vdash A(S) A^{\prime}: s$ then $\Gamma \vdash a$ (S) $a^{\prime}: A$ iff $\Gamma \vdash a$ © $a^{\prime}: A^{\prime}$.
(2) If $\Gamma \vdash T \widehat{\widehat{S}} T^{\prime}: s$ then $\Gamma \vdash t \widehat{\widehat{S}} t^{\prime}: T$ iff $\Gamma \vdash t \widehat{(\widehat{S})} t^{\prime}: T^{\prime}$.

Proof. Simultaneously induction in $A \in s$ and $T \in s$, resp. We show the "if" direction, the "only if" follows analogously. The interesting case is the one of functions.
Case

$$
\begin{aligned}
& \Delta \vdash U \widehat{\widehat{S}} U^{\prime}: s_{1} \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\text { © }} u^{\prime} \star U \Longrightarrow \Gamma \vdash T[u / x] \widehat{\text { © }} T^{\prime}\left[u^{\prime} / x\right]: s_{2} \\
& \frac{\Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T:=:\left(x \star U^{\prime}\right) \xrightarrow{s_{1}, s_{2}} T^{\prime}: s_{3}}{\Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T(S)\left(x \star U^{\prime}\right) \xrightarrow{s_{1}, s_{2}} T^{\prime}: s_{3}} \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\widehat{S}} u^{\prime} \star U \Longrightarrow \Gamma \vdash f^{\star} u \widehat{\widehat{S}} f^{\prime \star} u^{\prime}: T[u / x] \\
& \Delta \vdash f:=: f^{\prime}:(x \star U) \xrightarrow{s, s^{\prime}} T \\
& \Delta \vdash f(S) f^{\prime}:(x \star U) \xrightarrow{s, s^{\prime}} T
\end{aligned}
$$

First, $\Delta \vdash f:=: f^{\prime}:\left(x \star U^{\prime}\right) \xrightarrow{s, s^{\prime}} T^{\prime}$, holds because of the conversion rule for typing and equality. Now assume arbitrary $\Gamma \leq \Delta$ and $\Gamma \vdash u \widehat{(\mathbb{S})} u^{\prime} \star U^{\prime}$ and show $\Gamma \vdash f^{\star} u \widehat{(\mathbb{S}}$ $f^{\prime \star} u^{\prime}: T^{\prime}[u / x]$. By induction hypothesis on $U \in s_{1}$ we have $\Gamma \vdash u \widehat{\mathbb{S}} u^{\prime} \star U$, thus, $\Gamma \vdash f^{\star} u \widehat{(S)} f^{\prime \star} u^{\prime}: T[u / x]$ by assumption. By induction hypothesis on $T[u / x] \in s_{2}$ we obtain $\Gamma \vdash f^{\star} u \widehat{\widehat{S}} f^{\prime \star} u^{\prime}: T^{\prime}[u / x]$.

Lemma 4.3 (Symmetry and Transitivity). Let $\Delta \vdash T \widehat{(\mathbb{S}} T: s$.
(1) If $\Delta \vdash t \widehat{(\widehat{)}} t^{\prime}: T$ then $\Delta \vdash t^{\prime} \widehat{\widehat{S}} t: T$.
(2) If $\Delta \vdash t_{1} \widehat{\mathbb{S}} t_{2}: T$ and $\Delta \vdash t_{2} \widehat{\mathbb{S}} t_{3}: T$ then $\Delta \vdash t_{1} \widehat{\mathbb{S}} t_{3}: T$.

Proof. We generalize the two statements to whnfs $\Delta \vdash A$ (S) $A: s$ and prove all four statements simultaneously by induction in $A \in s$ and $T \in s$, resp.
Case Let us look at the case for functions.

$$
\begin{aligned}
& \Delta \vdash U \widehat{\mathbb{S}} U: s_{1} \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\mathbb{S}} u^{\prime} \star U \Longrightarrow \Gamma \vdash T[u / x] \widehat{\mathbb{S}} T\left[u^{\prime} / x\right]: s_{2} \\
& \Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T:=:(x \star U) \xrightarrow{s_{1, s s_{2}}} T: s_{3} \\
& \Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T \text { (S) }(x \star U) \xrightarrow{s_{1}, s_{2}} T: s_{3}
\end{aligned}
$$

Case Symmetry:

$$
\begin{gathered}
\forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\mathrm{~S}} u^{\prime} \star U \Longrightarrow \Gamma \vdash f^{\star} u \widehat{\mathrm{~S}} f^{\prime \star} u^{\prime}: T[u / x] \\
\Delta \vdash f:=: f^{\prime}:(x \star U) \rightarrow T
\end{gathered}
$$

To show $\Delta \vdash f^{\prime}$ (S) $f:(x \star U) \rightarrow T$, assume arbitrary $\Gamma \leq \Delta$ and $\Gamma \vdash u^{\prime} \widehat{\mathbb{S}} u \star U$ and show $\Gamma \vdash f^{\prime \star} u^{\prime} \widehat{\widehat{S}} f^{\star} u: T\left[u^{\prime} / x\right]$. By induction hypothesis on $U \in s_{2}$, with weakened $\Gamma \vdash U \widehat{\widehat{S}} U: s_{1}$, we have $\Gamma \vdash u \widehat{\mathbb{S}} u^{\prime} \star U$, thus, $\Gamma \vdash f^{\star} u \widehat{\widehat{S}} f^{\prime \star} u^{\prime}: T[u / x]$ by assumption. Using symmetry and transitivity on $U$ we obtain $\Gamma \vdash u \widehat{\mathbb{S}} u \star U$, thus, $\Gamma \vdash T[u / x] \widehat{\widehat{S}} T[u / x]: s_{2}$. By induction hypothesis on $T[u / x] \in s_{2}$ we apply symmetry to obtain $\Gamma \vdash f^{\prime \star} u^{\prime} \widehat{(\widehat{S}} f^{\star} u: T[u / x]$, and since $\Gamma \vdash T[u / x] \widehat{\text { © }} T\left[u^{\prime} / x\right]: s_{2}$ we conclude by type conversion (Lemma 4.2).
Case Transitivity:

$$
\left.\begin{array}{rl}
\forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\mathbb{S}} u^{\prime} \star U \Longrightarrow & \Gamma \vdash f_{1} \star u \widehat{\widehat{S}} f_{2} \star u^{\prime}: T[u / x] \\
\Delta \vdash f_{1}:=: f_{2}:(x \star U) \xrightarrow{s, s^{\prime}} T
\end{array}\right] .
$$

We wish to prove that $\Delta \vdash f_{1}(S) f_{3}:(x \star U) \xrightarrow{s, s^{\prime}} T$. We get $\Delta \vdash f_{1}:=: f_{3}:(x \star U) \xrightarrow{s, s^{\prime}} T$ immediately by transitivity of definitional equality. Given $\Gamma \leq \Delta$ and $\Gamma \vdash u \widehat{(\mathbb{S}} u^{\prime} \star U$, we need to show that $\Gamma \vdash f_{1}{ }^{\star} u \widehat{(\widehat{S}} f_{3}{ }^{\star} u^{\prime}: T[u / x]$.
As $\Gamma \vdash \__{-} \widehat{\mathbb{S}} \_: U$ is a PER by induction hypothesis, we have $\Gamma \vdash u \widehat{\mathbb{S}} u \star U$, which entails $f_{1}{ }^{\star} u \widehat{\text { © }} f_{2}{ }^{\star} u: T[u / x]$. From $\Gamma \vdash u \widehat{\text { © }} u^{\prime} \star U$ also have $\Gamma \vdash f_{2}{ }^{\star} u \widehat{\text { © }} f_{3}{ }^{\star} u^{\prime}$ : $T[u / x]$, which allows to conclude $\Gamma \vdash f_{1}{ }^{\star} u \widehat{\widehat{S}} f_{3}{ }^{\star} u^{\prime}: T[u / x]$ by transitivity at $T[u / x]$. Case Now, we consider function spaces:

## Case Transitivity:

$$
\begin{aligned}
& \Delta \vdash U_{1} \widehat{\mathbb{S}} U_{2}: s_{1} \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\widehat{S}} u^{\prime} \star U_{1} \Longrightarrow \Gamma \vdash T_{1}[u / x] \widehat{\widehat{S}} T_{2}\left[u^{\prime} / x\right]: s_{2} \\
& \Delta \vdash\left(x \star U_{1}\right) \xrightarrow{s_{1}, s_{2}} T_{1}:=:\left(x \star U_{2}\right) \xrightarrow{s_{1}, s_{2}} T_{2}: s_{3} \\
& \Delta \vdash\left(x \star U_{1}\right) \xrightarrow{s_{1}, s_{2}} T_{1}\left(\mathbb{S}\left(x \star U_{2}\right) \xrightarrow{s_{1, s_{2}}} T_{2}: s_{3}\right.
\end{aligned}
$$

$$
\begin{aligned}
& \Delta \vdash U_{2} \widehat{\mathbb{S}} U_{3}: s_{1} \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\mathbb{S}} u^{\prime} \star U_{2} \Longrightarrow \Gamma \vdash T_{2}[u / x] \widehat{\mathbb{S}} T_{3}\left[u^{\prime} / x\right]: s_{2} \\
& \quad \Delta \vdash\left(x \star U_{2}\right)^{s_{1}, s_{2}} T_{2}:=:\left(x \star U_{3}\right) \xrightarrow{s_{1}, s_{2}} T_{3}: s_{3} \\
& \quad \Delta \quad{ }^{s_{1}, s_{2}}
\end{aligned}
$$

By transitivity we have $\Delta \vdash\left(x \star U_{1}\right) \rightarrow T_{1}:=:\left(x \star U_{3}\right) \rightarrow T_{3}: s_{3}$ and $\Delta \vdash U_{1} \widehat{(\mathbb{S}} U_{3}: s_{1}$ by induction hypothesis on $s_{1}$.
Note that this is where the arrow sort annotations are useful. Without them we would not know that the sorts in both derivations are equal. We could have $\Delta \vdash U_{1} \widehat{\text { © }} U_{2}: s_{1}$ and $\Delta \vdash U_{2} \widehat{\text { © }} U_{3}: s_{1}^{\prime}$ for apparently unrelated $s_{1}$ and $s_{1}^{\prime}$, and would therefore be unable to use transitivity.
Given $\Gamma \leq \Delta$ and $\Gamma \vdash u \widehat{\widehat{S}} u^{\prime} \star U_{1}$, we need to show that $\Gamma \vdash T_{1}[u / x] \widehat{\widehat{S}} T_{3}\left[u^{\prime} / x\right]: s_{3}$. As $\widehat{\text { S }}$ at type $U$ is a PER by induction hypothesis, we have $\Gamma \vdash u \widehat{\text { S }} u \star U_{1}$, from which we can deduce $\Gamma \vdash T_{1}[u / x] \widehat{\text { S }} T_{2}[u / x]: s_{2}$. By conversion using $\Delta \vdash U_{1} \widehat{\text { © }} U_{2}: s_{1}-$ weakened at $\Gamma$ - we have $\Gamma \vdash u \widehat{(\mathbb{S}} u^{\prime} \star U_{2}$, which implies $\Gamma \vdash T_{2}[u / x] \widehat{\widehat{S}} T_{3}\left[u^{\prime} / x\right]: s_{2}$. This allows us to conclude by transitivity at type $s_{2}$.

In the following we show that the variables are in the logical relation, i. e., $\Delta \vdash x$ (S $x$ : $\Delta(x)$ for well-formed contexts $\Delta$. As usual, this statement has to be generalized to neutrals $n$ to be proven inductively.
Lemma 4.4 (Into the logical relation). Let $T \in s$. If $\Delta \vdash n:=: n^{\prime} \star T$ then $\Delta \vdash n \widehat{(S)} n^{\prime} \star T$.
Proof. By induction on $T \in s$.
Case $N \in s$ and $\Delta \vdash n:=: n^{\prime} \star N$. Then $\Delta \vdash n$ (S) $n^{\prime} \star N$ by cases on $\star$, unfolding definitions.
Case $s \in s^{\prime}$ and $\Delta \vdash N:=: N^{\prime} \star s$. Then $\Delta \vdash N$ (S) $N^{\prime} \star s$ by cases on $\star$.
Case $(x \star U) \rightarrow T \in s_{3}$ and $\Delta \vdash n:=: n^{\prime} \star_{0}(x \star U) \rightarrow T$.
First, the case for $\star_{0}=:$. We have $\Delta \vdash n:=: n^{\prime}:(x \star U) \rightarrow T$. Assume arbitrary $\Gamma \leq \Delta$ and $\Gamma \vdash u \widehat{\widehat{S}} u^{\prime} \star U$, which yields $\Gamma \vdash u:=: u^{\prime} \star U$ and $\Gamma \vdash T[u / x] \widehat{\widehat{S}} T[u / x]: s_{2}$. By weakening, $\Gamma \vdash n^{\star} u:=: n^{\prime \star} u^{\prime}: T[u / x]$, thus, by induction hypothesis, $\Gamma \vdash n^{\star} u$ © $n^{\prime \star} u^{\prime}: T[u / x]$, q.e.d.

The case for $\star_{0}=\div$ proceeds analogously.
4.3. Validity in the Model. We now extend our logical relation $\widehat{\mathbb{S}}$ to substitutions, by induction on the destination context.

$$
\frac{\Delta \vdash \sigma \widehat{\mathbb{S}} \sigma^{\prime}: \Gamma \quad \Delta \vdash \sigma(x) \widehat{\mathbb{S}} \sigma^{\prime}(x) \star U \sigma}{\Delta \vdash \sigma \widehat{\mathbb{S}} \sigma^{\prime}: \diamond} \quad \frac{\Delta \widehat{\mathbb{S}} \sigma^{\prime}: \Gamma \cdot x \star U}{\Delta}
$$

This relation inherits weakening from $\widehat{\widehat{S}}$ for terms.
We then define the context $(\Vdash \Gamma)$, type $\left(\Gamma \Vdash T=T^{\prime}\right)$ and term $\left(\Gamma \Vdash t=t^{\prime}: T\right)$ validity relations, by induction on the length of contexts.

$$
\begin{array}{ccc}
\frac{\Vdash \vdash}{\Vdash \diamond} & \frac{\Gamma \Vdash \Gamma}{\Vdash \Gamma \cdot x \star U} & \frac{\Gamma \Vdash T=T^{\prime}: s}{\Gamma \Vdash T=T^{\prime}}
\end{array} \quad \frac{\Gamma \Vdash T=T}{\Gamma \Vdash T}
$$

Because of its asymmetric definition, the logical relation on substitutions may not be a PER in general, but it is for valid contexts.
Lemma 4.5 (Substitution relation is a PER). If $\Vdash \Gamma$, then $\Delta \vdash_{-} \widehat{\mathrm{S}} \mathrm{H}_{-}: \Gamma$ is symmetric and transitive.

Proof. By induction on $\Gamma$. We demonstrate symmetry for the case $\Vdash \Gamma . x \star U$.

$$
\frac{\Delta \vdash \sigma \widehat{\mathrm{S}} \sigma^{\prime}: \Gamma \quad \Delta \vdash \sigma(x) \widehat{\mathrm{S}} \sigma^{\prime}(x) \star U \sigma}{\Delta \vdash \sigma \widehat{\widehat{S}} \sigma^{\prime}: \Gamma \cdot x \star U}
$$

By induction hypothesis, $\Delta \vdash \sigma^{\prime} \widehat{\mathrm{S}} \sigma: \Gamma$, and by symmetry of $\widehat{\mathrm{S}}$ for terms (Lemma 4.3), $\Delta \vdash \sigma^{\prime}(x) \widehat{\widehat{S}} \sigma(x) \star U \sigma$. We instantiate $\Gamma \Vdash U$ to $\Delta \vdash U \sigma \widehat{\widehat{S}} U \sigma^{\prime}: s$ and conclude $\Delta \vdash \sigma^{\prime}(x) \widehat{\widehat{S}} \sigma(x) \star U \sigma^{\prime}$ by conversion (Lemma 4.2).
Lemma 4.6 (Validity is a PER). The relation $\Gamma \Vdash^{-}=_{-}: T$ is symmetric and transitive.
Proof. Symmetry requires symmetry of $\widehat{\widehat{S}}$ for substitutions and conversion with $\Delta \vdash T \sigma \widehat{\mathrm{~S}}$ $T \sigma^{\prime}: s^{\prime}$, similar as in Lemma 4.5.

We demonstrate transitivity in detail. Given $\Gamma \Vdash t_{1}=t_{2}: T$ and $\Gamma \Vdash t_{2}=t_{3}: T$ we show $\Gamma \Vdash t_{1}=t_{3}: T$. Clearly, $\Vdash \Gamma$ and $\Gamma \Vdash T$ or $T=s$ by one of our two assumptions. Assume arbitrary $\Delta \vdash \sigma \widehat{\widehat{S}} \sigma^{\prime}: \Gamma$ and show $\Delta \vdash t_{1} \sigma \widehat{\widehat{S}} t_{3} \sigma^{\prime}: T \sigma$. By Lemma 4.5, $\Delta \vdash \sigma \widehat{\widehat{S}} \sigma: \Gamma$, thus $\Delta \vdash t_{1} \sigma \widehat{\widehat{S}} t_{2} \sigma: T \sigma$. Also, $\Delta \vdash t_{2} \sigma \widehat{\widehat{S}} t_{3} \sigma^{\prime}: T \sigma$ which entails our goal by transitivity of $\widehat{\widehat{S}}$ (Lemma 4.3).
Lemma 4.7 (Function type injectivity is valid). If $\Gamma \Vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T=\left(x \star U^{\prime}\right) \xrightarrow{s_{1}^{\prime}, s_{2}^{\prime}} T^{\prime}$ then $s_{1}=s_{1}^{\prime}$ and $s_{2}=s_{2}^{\prime}$ and $\Gamma \Vdash U=U^{\prime}: s_{1}$ and $\Gamma . x \star U^{\prime} \Vdash T=T^{\prime}: s_{2}$.
Proof. Assume arbitrary $\Delta \vdash \sigma \widehat{\mathrm{S}} \sigma^{\prime}: \Gamma$. We have $\Delta \vdash(x \star U \sigma) \xrightarrow{s_{1}, s_{2}} T \sigma \widehat{\mathrm{~S}}\left(x \star U^{\prime} \sigma^{\prime}\right) \xrightarrow{s_{1}^{\prime}, s_{2}^{\prime}}$ $T^{\prime} \sigma^{\prime}: s_{3}$, thus by definition $s_{1}=s_{1}^{\prime}$ and $s_{2}=s_{2}^{\prime}$ and $\Delta \vdash U^{\prime} \sigma^{\prime} \widehat{\mathbb{S}} U \sigma: s_{1}$ —note that sorts are closed and therefore invariant by substitution. By symmetry of $\widehat{\mathrm{S}}$, and since $\Delta, \sigma, \sigma^{\prime}$ were arbitrary, we have $\Gamma \Vdash U=U^{\prime}: s_{1}$.

Further, assume arbitrary $\Delta \vdash u \widehat{\widehat{S}} u^{\prime} \star U^{\prime} \sigma$ and let $\rho=(\sigma, u / x)$ and $\rho^{\prime}=\left(\sigma^{\prime}, u^{\prime} / x\right)$. Note that w.l.o.g., $x \notin \operatorname{dom}(\Gamma)$ and $x \notin \mathrm{FV}\left(U^{\prime}\right)$ and $\Delta \vdash \rho \widehat{\mathbb{S}} \rho^{\prime}: \Gamma . x \star U^{\prime}$. We have $\Delta \vdash T \rho \widehat{\mathbb{S}} T^{\prime} \rho^{\prime}: s_{2}$ and since $\rho, \rho^{\prime}$ were arbitrary, $\Gamma . x \star U^{\prime} \Vdash T=T^{\prime}: s_{2}$.

Lemma 4.8 (Context satisfiable). If $\Vdash \Gamma$ then $\vdash \Gamma$ and $\Gamma \vdash \mathrm{id} \widehat{(S)}$ id : $\Gamma$.
Proof. By induction on $\Gamma$. The $\diamond$ case is immediate. In the $\Gamma . x \star U$ case, given

$$
\frac{\Vdash \Gamma \quad \Gamma \Vdash U}{\Vdash \Gamma \cdot x \star U}
$$

we can use inference

$$
\frac{\Gamma \cdot x \star U \vdash \mathrm{id} \widehat{\widehat{S}} \text { id }: \Gamma \quad \Gamma \cdot x \star U \vdash \mathrm{id}(x) \widehat{\widehat{S}} \mathrm{id}(x) \star U \mathrm{id}}{\Gamma \cdot x \star U \vdash \mathrm{id} \widehat{\widehat{S}} \text { id }: \Gamma \cdot x \star U} .
$$

From the induction hypothesis $\Gamma \vdash$ id $\widehat{\widehat{S}}$ id $: \Gamma$, we obtain the first premise by weakening of $\widehat{\widehat{S}}$. It also yields $\Gamma \vdash U$ id $:$ sid for some $s$ by definition of $\Gamma \Vdash U$. Using induction hypothesis, $\vdash \Gamma$, this entails $\vdash \Gamma . x \star U$. Further, $\Gamma . x \star U \vdash x=x \star U$, and since trivially $\Gamma . x \star U \vdash x \longleftrightarrow x \star U$, we can derive $\Gamma . x \star U \vdash x \widehat{\text { © }} x \star U$, by the Lemma 4.4. This concludes the second premise $\Gamma . x \star U \vdash \mathrm{id}(x) \widehat{\text { © }} \mathrm{id}(x) \star U \mathrm{id}$.

We can now show that every equation valid in the model is derivable in IITT.
Theorem 4.9 (Completeness of IITT rules). If $\Gamma \Vdash t=t^{\prime}: T$ then both $\Gamma \vdash t: T$ and $\Gamma \vdash t^{\prime}: T$ and $\Gamma \vdash t=t^{\prime}: T$ and $\Gamma \vdash T$.
Proof. Using Lemma 4.8 we obtain $\Gamma \vdash t \widehat{\mathrm{~S}} t^{\prime}: T$, which entails $\Gamma \vdash t, t^{\prime}: T$ and $\Gamma \vdash t=$ $t^{\prime}: T$. Analogously, since our assumption entails $\Gamma \Vdash T$ by definition, we get $\Gamma \vdash T$.
4.4. Fundamental theorem. We prove a series of lemmata which constitute parts of the fundamental theorem for the Kripke logical relation.
Lemma 4.10 (Resurrection). If $\Vdash \Gamma$ and $\Delta \vdash \sigma \widehat{(S)} \sigma^{\prime}: \Gamma$ then $\Delta \div \vdash \sigma \widehat{(S)} \sigma: \Gamma^{\doteqdot}$ and $\Delta^{\div} \vdash \sigma^{\prime} \widehat{\mathbb{S}} \sigma^{\prime}: \Gamma^{\doteqdot}$.
Proof. By induction on $\Gamma$, the interesting case being

$$
\frac{\Delta \vdash \sigma \widehat{\mathbb{S}} \sigma^{\prime}: \Gamma \quad \Delta \vdash \sigma(x) \widehat{\widehat{S}} \sigma^{\prime}(x) \star U \sigma}{\Delta \vdash \sigma \widehat{\mathbb{S}} \sigma^{\prime}: \Gamma \cdot x \star U} .
$$

First, we show $\Delta^{\doteqdot} \vdash \sigma \widehat{(\mathbb{S}} \sigma:\left(\Gamma^{\doteqdot} \cdot x: U\right)$. By induction hypothesis $\Delta^{\doteqdot} \vdash \sigma \widehat{\mathrm{S}} \sigma: \Gamma^{\mp}$, and by definition, $\Delta^{\div} \vdash \sigma(x) \widehat{(\mathbb{S}} \sigma(x): U \sigma$. This immediately entails our goal.

For the second goal $\Delta^{\doteqdot} \vdash \sigma^{\prime} \widehat{\widehat{S}} \sigma^{\prime}:\left(\Gamma^{\doteqdot} \cdot x: U\right)$, observe that $\Gamma \Vdash U$, hence $\Delta \vdash U \sigma \widehat{\mathbb{S}}$ $U \sigma^{\prime}: s$ for some sort $s$. Thus, we can cast our hypothesis $\Delta \vdash \sigma^{\prime}(x) \widehat{\mathbb{S}} \sigma^{\prime}(x): U \sigma$ to $U \sigma^{\prime}$ and conclude analogously.
Corollary 4.11. If $\Gamma^{\star} \Vdash u: U$ and $\Delta \vdash \sigma \widehat{\text { © }} \sigma^{\prime}: \Gamma$ then $\Delta \vdash u \sigma \widehat{\mathbb{S}} u \sigma^{\prime} \star U \sigma$.
Proof. In case $\star=$ : it holds by definition, but we need resurrection for $\star=\div$. If $\Delta \vdash \sigma \widehat{(S)}$ $\sigma^{\prime}: \Gamma$, then by resurrection (Lemma 4.10) we have $\Delta^{\doteqdot} \vdash \sigma \widehat{\mathbb{S}} \sigma: \Gamma^{\mp}$, so from $\Gamma^{\doteqdot} \Vdash u: U$ we deduce $\Delta^{\div} \vdash u \sigma \widehat{(\widehat{S}} u \sigma: U \sigma$. Analogously we get $\Delta^{\div} \vdash u \sigma^{\prime} \widehat{\widehat{S}} u \sigma^{\prime}: U \sigma^{\prime}$ which we cast to $\Delta^{\div} \vdash u \sigma^{\prime} \widehat{(S)} u \sigma^{\prime}: U \sigma$.
Lemma 4.12 (Validity of $\beta$-reduction).

$$
\frac{\Gamma \cdot x \star U \Vdash t: T \quad \Gamma^{\star} \Vdash u: U}{\Gamma \Vdash(\lambda x \star U \cdot t)^{\star} u=t[u / x]: T[u / x]}
$$

Proof. $\Vdash \Gamma$ is contained in the first hypothesis $\Gamma \Vdash u \star U$. Then, given $\Delta \vdash \rho \widehat{\mathbb{S}} \rho^{\prime}: \Gamma$ we need to show $\Delta \vdash(\lambda x \star U \cdot t) \rho^{\star} u \rho \widehat{\widehat{S}} t\left(\rho^{\prime}, u \rho^{\prime} / x\right): T(\rho, u \rho / x)$ and also $\Delta \vdash T[u / x] \rho \widehat{\mathrm{S}}$ $T[u / x] \rho^{\prime}: s$ for some $s$ (the latter to get $\left.\Gamma \Vdash T[u / x]\right)$.

Let $\sigma=(\rho, u \rho / x)$ and $\sigma^{\prime}=\left(\rho^{\prime}, u \rho^{\prime} / x\right)$. From the second hypothesis and Cor.4.11we get $\Delta \vdash u \rho \widehat{\widehat{S}} u \rho^{\prime} \star U \rho$, which gives $\Delta \vdash \sigma \widehat{\widehat{S}} \sigma^{\prime}: \Gamma . x \star U$. By instantiating the first hypothesis we get $\Delta \vdash t \sigma \widehat{\widehat{S}} t \sigma^{\prime}: T \sigma$, and also (from the premise $\Gamma . x \star U \Vdash T$ ) $\Delta \vdash T \sigma=T \sigma^{\prime}$, which gives $\Gamma \Vdash T[u / x]$.

Finally, from $\Delta \vdash t \sigma \widehat{\text { S }} t \sigma^{\prime}$ we get the desired $\Delta \vdash(\lambda x \star U \cdot t) \rho^{\star} u \rho \widehat{\text { © }} t \sigma^{\prime}: T \sigma$, as $\widehat{\text { © }}$ is closed by weak head expansion to well-typed $\Delta \vdash(\lambda x \star U . t) \rho \star u \rho: T \sigma$.

Lemma 4.13 (Validity of $\eta$ ).

$$
\frac{\Gamma \Vdash t:(x \star U) \rightarrow T}{\Gamma \Vdash t=\lambda x \star U \cdot t^{\star} x:(x \star U) \rightarrow T}
$$

Proof. $\Vdash \Gamma$ and $\Gamma \Vdash(x \star U) \rightarrow T$ are direct consequences of our hypothesis. Given $\Delta \vdash \rho \widehat{\mathbb{S}}$ $\rho^{\prime}: \Gamma$, we need to show $\Delta \vdash t \rho \widehat{(\mathbb{S}}\left(\lambda x \star U \cdot t^{\star} x\right) \rho^{\prime}:((x \star U) \rightarrow T) \rho$. W.l. o. g., $x$ is not free in the domain nor range of substitutions $\rho$ and $\rho^{\prime}$, thus with $t^{\prime}:=t \rho, t^{\prime \prime}:=t \rho^{\prime}, U^{\prime}:=U \rho, U^{\prime \prime}:=$ $U \rho^{\prime}, T^{\prime}:=T \rho$ and $T^{\prime \prime}:=T \rho^{\prime}$ it is sufficient to show $\Delta \vdash t^{\prime} \widehat{\mathbb{S}} \lambda x \star U^{\prime \prime} \cdot t^{\prime \prime *} x:\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$.

First, given $\left(\Delta^{\prime}, u, u^{\prime}\right)$ such that $\Delta^{\prime} \leq \Delta$ and $\Delta^{\prime} \vdash u \widehat{\widehat{S}} u^{\prime} \star U^{\prime}$, we show $\Delta^{\prime} \vdash t^{\prime \star} u \widehat{\widehat{S}}$ $\left(\lambda x \star U^{\prime \prime} . t^{\prime \prime \star} x\right)^{\star} u^{\prime}: T^{\prime}[u / x]$. Our hypothesis $\Gamma \Vdash t:(x \star U) \rightarrow T$ entails $\Delta \vdash t \rho \widehat{\widehat{S}} t \rho^{\prime}:$ $((x \star U) \rightarrow T) \rho$, that is to say $\Delta \vdash t^{\prime} \widehat{(S)} t^{\prime \prime}:\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$. This logical relation at a function type, when instantiated to $\left(\Delta^{\prime}, u, u^{\prime}\right)$, gives us $\Delta^{\prime} \vdash t^{\prime \star} u \widehat{\widehat{S}} t^{\prime \prime *} u^{\prime}: T^{\prime}[u / x]$, which weak-head expands to the desired goal.

Second, we show $\Delta \vdash t^{\prime}:=: \lambda x \star U^{\prime \prime} . t^{\prime \prime *} x:\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$.

- $\Gamma \vdash t^{\prime}:\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$ is a simple consequence of our hypothesis $\Gamma \Vdash t:(x \star U) \rightarrow T$.
- $\Gamma \vdash \lambda x \star U^{\prime \prime} . t^{\prime \prime \star} x:\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$ has the following proof:
- $\Delta \vdash t^{\prime}=\lambda x \star U^{\prime \prime} . t^{\prime \prime \star} x:\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$. The $\eta$-rule of definitional equality gives us $\Delta \vdash t^{\prime \prime}=\lambda x \star U^{\prime \prime} . t^{\prime \prime *} x:\left(x \star U^{\prime \prime}\right) \rightarrow T^{\prime \prime}$. From $\Gamma \Vdash(x \star U) \rightarrow T$ we can convert it to the type $\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$, and then conclude by transitivity using $\Delta \vdash t^{\prime}=t^{\prime \prime}$ : $\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$, which is a direct consequence of $\Gamma \Vdash t:(x \star U) \rightarrow T$.

Lemma 4.14 (Validity of function equality).

$$
\frac{\Gamma \Vdash U=U^{\prime} \quad \Gamma \cdot x \star U \Vdash t=t^{\prime}: T}{\Gamma \Vdash(\lambda x \star U \cdot t)=\left(\lambda x \star U^{\prime} \cdot t^{\prime}\right):(x \star U) \rightarrow T}
$$

Proof. Again $\Vdash \Gamma$ and $\Gamma \Vdash(x \star U) \rightarrow T$ are simple consequences of our hypotheses. Given $\Delta \vdash \rho \widehat{\mathbb{S}} \rho^{\prime}: \Gamma$ (w.l.o.g., $x$ is not free in $\rho, \rho^{\prime}$ domain or range), we need to show
$\Delta \vdash(\lambda x \star U \rho . t \rho) \widehat{(S)}\left(\lambda x \star U^{\prime} \rho^{\prime} . t^{\prime} \rho^{\prime}\right):((x \star U \rho) \rightarrow T \rho)$. We will skip the proof of $\Delta \vdash$ $(\lambda x \star U \rho . t \rho):=:\left(\lambda x \star U^{\prime} \rho^{\prime} . t^{\prime} \rho^{\prime}\right):((x \star U \rho) \rightarrow T \rho)$, as it is similar to the corresponding part of the $\eta$-validity lemma.

Given $\left(\Delta^{\prime}, u, u^{\prime}\right)$ such that $\Delta^{\prime} \leq \Delta$ and $\Delta^{\prime} \vdash u \widehat{\text { S }} u^{\prime} \star U \rho$, we have to show that $\Delta^{\prime} \vdash(\lambda x \star U \rho \cdot t \rho)^{\star} u \widehat{(S)}\left(\lambda x \star U^{\prime} \rho^{\prime} \cdot t^{\prime} \rho^{\prime}\right)^{\star} u^{\prime}: T \rho[u / x]$. Let $\sigma=(\rho, u / x)$ and $\sigma^{\prime}=\left(\rho^{\prime}, u^{\prime} / x\right)$. As we supposed $\Delta^{\prime} \vdash u \widehat{\widehat{S}} u^{\prime} \star U \rho$, we have $\Delta^{\prime} \vdash \sigma \widehat{\widehat{S}} \sigma^{\prime}: \Gamma . x \star U \rho$. Instantiating the second hypothesis with $\Delta^{\prime}, \sigma, \sigma^{\prime}$ therefore gives us $\Delta^{\prime} \vdash t \sigma=t^{\prime} \sigma^{\prime}: T \sigma$, which can also be written $\Delta^{\prime} \vdash t \rho[u / x] \widehat{(S)} t^{\prime} \rho^{\prime}\left[u^{\prime} / x\right]: T \rho[u / x]$, which is weak-head expansible to our goal.
Lemma 4.15 (Validity of irrelevant application).

$$
\frac{\Gamma \Vdash t=t^{\prime}:(x \div U) \rightarrow T \quad \Gamma^{\div} \Vdash u: U \quad \Gamma^{\div} \Vdash u^{\prime}: U}{\Gamma \Vdash t \div u=t^{\prime} \div u^{\prime}: T[u / x]}
$$

Proof. Assume arbitrary $\Delta \vdash \rho \widehat{\mathbb{S}} \rho^{\prime}: \Gamma$ and show $\Delta \vdash t \rho^{\circ} \dot{\tau} \rho \widehat{\widehat{S}} t^{\prime} \rho^{\prime} \div u^{\prime} \rho^{\prime}: T(\rho, u \rho / x)$. By the first hypothesis, it is sufficient to show $\Delta \vdash u \rho \widehat{\text { © }} u^{\prime} \rho^{\prime} \div U \rho$, which means $\Delta^{\div} \vdash$ $u \rho \widehat{\widehat{S}} u \rho: U \rho$ and $\Delta^{\div} \vdash u^{\prime} \rho^{\prime} \widehat{(S)} u^{\prime} \rho^{\prime}: U \rho$. By Resurrection (Lemma 4.10), $\Delta^{\div} \vdash \rho \widehat{\widehat{(S}}$ $\rho: \Gamma^{\mp}$, hence $\Delta^{\div} \vdash u \rho \widehat{\widehat{S}} u \rho: U \rho$ from the second hypothesis. Analogously, we obtain $\Delta^{\div} \vdash u^{\prime} \rho^{\prime} \widehat{\widehat{S}} u^{\prime} \rho^{\prime}: U \rho^{\prime}$ from the third hypothesis which we can cast to $U \rho$ by virtue of $\Gamma \Vdash U$ which we get from $\Gamma \Vdash(x \div U) \rightarrow T$ by Lemma 4.7,

Theorem 4.16 (Fundamental theorem of logical relations).
(1) If $\vdash \Gamma$ then $\Vdash \Gamma$.
(2) If $\Gamma \vdash t: T$ then $\Gamma \Vdash t: T$.
(3) If $\Gamma \vdash t=t^{\prime}: T$ then $\Gamma \Vdash t=t^{\prime}: T$.

Proof. By induction on the derivation.
As a simple corollary we obtain syntactic validity, namely that definitional equality implies well-typedness and well-typedness implies well-formedness of the involved type. This lemma could have been proven purely syntactically, but the syntactic proof requires a sequence of carefully arranged lemmata like context conversion, substitution, functionality, and inversion on types HP05, AC07. Our "sledgehammer" semantic argument is built into the Kripke logical relation, in the spirit of Goguen Gog00.

Corollary 4.17 (Syntactic validity).
(1) If $\Gamma \vdash t: T$ then $\Gamma \vdash T$.
(2) If $\Gamma \vdash t=t^{\prime}: T$ then $\Gamma \vdash t: T$ and $\Gamma \vdash t^{\prime}: T$.

Proof. By the fundamental theorem, $\Gamma \vdash t=t^{\prime}: T$ implies $\Gamma \Vdash t=t^{\prime}: T$, which by Thm. 4.9 implies $\Gamma \vdash t, t^{\prime}: T$ and $\Gamma \vdash T$.

## 5. Meta-theoretic Consequences of the Model Construction

In this section, we explicate the results established by the Kripke model.
5.1. Admissibility of Substitution. Goguen Gog00 observes that admissibility of substitution for the syntactic judgements can be inherited from the Kripke logical relation, which is closed under substitution by its very definition.

To show that the judgements of IITT are closed under substitution we introduce relations $\Gamma \vdash \sigma: \Gamma^{\prime}$ for substitution typing and $\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}$ for substitution equality which are given inductively by the following rules:

$$
\begin{aligned}
& \frac{\vdash \Gamma}{\Gamma \vdash \sigma: \diamond} \quad \frac{\Gamma \vdash \sigma: \Gamma^{\prime} \quad \Gamma^{\prime} \vdash U \quad \Gamma \vdash \sigma(x) \star U \sigma}{\Gamma \vdash \sigma: \Gamma^{\prime} . x \star U} \\
& \frac{\vdash \Gamma}{\Gamma \vdash \sigma=\sigma^{\prime}: \diamond} \quad \frac{\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime} \quad \Gamma^{\prime} \vdash U \quad \Gamma \vdash \sigma(x)=\sigma^{\prime}(x) \star U \sigma}{\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime} \cdot x \star U}
\end{aligned}
$$

Substitution typing and equality are closed under weakening.
Semantically, substitutions are explained by environments. We define substitution validity as follows, again in rule form but not inductively:

$$
\frac{\Gamma \Vdash \sigma=\sigma: \Gamma^{\prime}}{\Gamma \Vdash \sigma: \Gamma^{\prime}} \quad \frac{\forall \Delta \Vdash \rho \widehat{\mathbb{S}} \rho^{\prime}: \Gamma . \Delta \Vdash \sigma \cdot \Delta \stackrel{\rightharpoonup}{\mathbb{S}} \sigma^{\prime} \rho^{\prime}: \Gamma^{\prime}}{\Gamma \Vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}}
$$

Lemma 5.1 (Fundamental lemma for substitutions).
(1) If $\Gamma \vdash \sigma: \Gamma^{\prime}$ then $\Gamma \Vdash \sigma: \Gamma^{\prime}$.
(2) If $\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}$ then $\Gamma \Vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}$.

Proof. We demonstrate 2 by induction on $\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}$.
Case

$$
\frac{\vdash \Gamma}{\Gamma \vdash \sigma=\sigma^{\prime}: \diamond}
$$

We have $\Vdash \Gamma$ by Thm. 4.16 and $\Vdash \diamond$ trivially. Also, $\Delta \vdash \sigma \rho \widehat{\widehat{S}} \sigma^{\prime} \rho^{\prime}: \diamond$ trivially for any $\Delta \vdash \rho \widehat{\mathbb{S}} \rho^{\prime}: \Gamma$.
Case

$$
\frac{\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime} \quad \Gamma^{\prime} \vdash U \quad \Gamma \vdash \sigma(x)=\sigma^{\prime}(x) \star U \sigma}{\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime} \cdot x \star U}
$$

We have $\Vdash \Gamma$ and $\Vdash \Gamma^{\prime}$ by induction hypothesis and $\Gamma^{\prime} \Vdash U$ by Thm. 4.16, thus, $\Vdash \Gamma^{\prime} \cdot x \star U$. Now assume arbitrary $\Delta \vdash \rho \widehat{\widehat{S}} \rho^{\prime}: \Gamma$ and show $\Delta \vdash \sigma \rho \widehat{\mathbb{S}} \sigma^{\prime} \rho^{\prime}: \Gamma^{\prime} . x \star U$. First, $\Delta \vdash \sigma \rho \widehat{\widehat{S}} \sigma^{\prime} \rho^{\prime}: \Gamma^{\prime}$ follows by induction hypothesis. The second subgoal $\Delta \vdash$ $(\sigma \rho)(x) \widehat{\text { © }}\left(\sigma^{\prime} \rho^{\prime}\right)(x) \star U \sigma \rho$ is just an instance of the second induction hypothesis.

Theorem 5.2 (Substitution and functionality).
(1) If $\Gamma \vdash \sigma: \Gamma^{\prime}$ and $\Gamma^{\prime} \vdash t: T$ then $\Gamma \vdash t \sigma: T \sigma$.
(2) If $\Gamma \vdash \sigma: \Gamma^{\prime}$. and $\Gamma^{\prime} \vdash t=t^{\prime}: T$ then $\Gamma \vdash t \sigma=t^{\prime} \sigma: T \sigma$.
(3) If $\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}$. and $\Gamma^{\prime} \vdash t: T$ then $\Gamma \vdash t \sigma=t \sigma^{\prime}: T \sigma$.
(4) If $\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}$. and $\Gamma^{\prime} \vdash t=t^{\prime}: T$ then $\Gamma \vdash t \sigma=t^{\prime} \sigma^{\prime}: T \sigma$.

Proof. We demonstrate 4, the other cases are just variations of the theme. First, from $\Gamma \vdash \sigma=\sigma^{\prime}: \Gamma^{\prime}$ we get $\Gamma \vdash \sigma \widehat{\widehat{S}} \sigma^{\prime}: \Gamma^{\prime}$ by the fundamental lemma for substitutions (Lemma [5.1), using the identity environment $\Gamma \vdash$ id $\widehat{\widehat{S}}$ id $: \Gamma$. Now, by the fundamental theorem on $\Gamma \vdash t=t^{\prime}: T$ we obtain $\Gamma \vdash t \sigma \widehat{\mathbb{S}} t^{\prime} \sigma^{\prime}: T \sigma$, which entails our goal $\Gamma \vdash t \sigma=$ $t^{\prime} \sigma^{\prime}: T \sigma$ by Thm. 4.9,
5.2. Context conversion. Context equality $\vdash \Gamma=\Gamma^{\prime}$ is defined inductively by the rules

$$
\overline{\vdash \diamond=\diamond} \quad \frac{\vdash \Gamma=\Gamma^{\prime} \quad \Gamma \vdash U=U^{\prime}}{\vdash \Gamma \cdot x \star U=\Gamma^{\prime} \cdot x \star U^{\prime}} .
$$

All declarative judgements are closed under context conversion. This fact is easy to prove by induction over derivations, but we get it as just a special case of substitution.
Lemma 5.3 (Identity substitution). If $\vdash \Gamma=\Gamma^{\prime}$ then $\Gamma \vdash \mathrm{id}=\mathrm{id}: \Gamma^{\prime}$.
Proof. By induction on $\vdash \Gamma=\Gamma^{\prime}$.
Case

$$
\frac{\vdash \Gamma=\Gamma^{\prime} \quad \Gamma \vdash U=U^{\prime}}{\vdash \Gamma \cdot x \star U=\Gamma^{\prime} \cdot x \star U^{\prime}}
$$

By induction hypothesis and weakening, $\Gamma . x \star U \vdash \mathrm{id}=\mathrm{id}: \Gamma^{\prime}$. Also, $\Gamma . x \star U \vdash x=x \star U$ and by conversion $\Gamma . x \star U \vdash x=x \star U^{\prime}$. Together, $\Gamma . x \star U \vdash \mathrm{id}=\mathrm{id}: \Gamma^{\prime} . x \star U^{\prime}$.

Theorem 5.4 (Context conversion). Let $\vdash \Gamma^{\prime}=\Gamma$.
(1) If $\Gamma \vdash t: T$ then $\Gamma^{\prime} \vdash t: T$.
(2) If $\Gamma \vdash t=t^{\prime}: T$ then $\Gamma^{\prime} \vdash t=t^{\prime}: T$.

Proof. By Thm. 5.2 with $\Gamma^{\prime} \vdash \mathrm{id}=\mathrm{id}: \Gamma$.
As a consequence, context equality is symmetric and transitive (we can trade $\Gamma \vdash U=$ $U^{\prime}$ for $\Gamma^{\prime} \vdash U=U^{\prime}$ ). Thus, context conversion can be applied in the other direction as well.
5.3. Inversion, injectivity, and type unicity. A condition for the decidability of type checking is the ability to invert typing derivations. The proof requires substitution.
Lemma 5.5 (Inversion).
(1) If $\Gamma \vdash x: T$ then $(x: U) \in \Gamma$ for some $U$ with $\Gamma \vdash U=T$.
(2) If $\Gamma \vdash \lambda x \star U . t: T$ then $\Gamma . x \star U \vdash t: T^{\prime}$ for some $T^{\prime}$ with $\Gamma \vdash(x \star U) \rightarrow T^{\prime}=T$.
(3) If $\Gamma \vdash t^{\star} u: T$ then $\Gamma \vdash t:(x \star U) \rightarrow T^{\prime}$ and $\Gamma \vdash u \star U$ for some $U, T^{\prime}$ with $\Gamma \vdash$ $T^{\prime}[u / x]=T$.
(4) If $\Gamma \vdash s: T$ then there is $\left(s, s^{\prime}\right) \in$ Axiom such that $\Gamma \vdash s^{\prime}=T$.
(5) If $\Gamma \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T^{\prime}: T$ then $\Gamma \vdash U: s_{1}$ and $\Gamma$. $x \star U \vdash T^{\prime}: s_{2}$, and for some $s_{3}$ we have $\Gamma \vdash s_{3}=T$ and $\left(s_{1}, s_{2}, s_{3}\right) \in$ Rule.
Proof. Each by induction on the typing derivation.
Remark 5.6. The need for inversion during type checking is the only good reason to have separate typing rules and not simply define typing $\Gamma \vdash t: T$ as the diagonal $\Gamma \vdash t=t: T$ of equality. While by a logical relation argument we will obtain a suitable inversion result for $\Gamma \vdash(x \star U) \rightarrow T=(x \star U) \rightarrow T$-the famous function type injectivity (Theorem 5.7)- it seems hard to get something similar for application $t u$.

Injectivity for function types w.r.t. typed equality is known to be tricky. It is connected to subject reduction and required for many meta-theoretic results. We harvest it from our Kripke model.

Theorem 5.7 (Function type injectivity). If $\Gamma \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T=\left(x \star U^{\prime}\right) \xrightarrow{s_{1}^{\prime}, s_{2}^{\prime}} T^{\prime}: s_{3}$ then $s_{1}=s_{1}^{\prime}$ and $s_{2}=s_{2}^{\prime}$ and $\Gamma \vdash U=U^{\prime}: s_{1}$ and $\Gamma . x \star U \vdash T=T^{\prime}: s_{2}$.

Proof. This follows from Lemma 4.7. Or we can prove it directly as follows: Since $\Gamma \vdash$ id $\widehat{\text { © }}$ id : $\Gamma$ we have by the fundamental theorem $\Gamma \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T \widehat{\mathbb{S}}\left(x \star U^{\prime}\right) \xrightarrow{s_{1}, s_{2}} T^{\prime}: s_{3}$ which by inversion yields first $s_{1}=s_{1}^{\prime}$ and $s_{2}=s_{2}^{\prime}$ and $\Gamma \vdash U \widehat{\widehat{S}} U^{\prime}: s_{1}$ and $\Gamma \vdash U=U^{\prime}: s_{1}$. Since $\Gamma . x \star U \vdash x \widehat{\widehat{S}} x \star U$, we also obtain $\Gamma . x \star U \vdash T \widehat{\widehat{S}} T^{\prime}: s_{2}$ and conclude $\Gamma . x \star U \vdash T=T^{\prime}: s_{2}$.

From the inversion lemma we can prove uniqueness of types, since we are dealing with a functional PTS, and we have function type injectivity.
Theorem 5.8 (Type unicity). If $\Gamma \vdash t: T$ and $\Gamma \vdash t: T^{\prime}$ then $\Gamma \vdash T=T^{\prime}$.
Proof. By induction on $t$, using inversion.
5.4. Normalization and Subject Reduction. An immediate consequence of the model construction is that each term has a weak head normal form and that typing and equality is preserved by weak head normalization.
Theorem 5.9 (Normalization and subject reduction). If $\Gamma \vdash t: T$ then $t \searrow a$ and $\Gamma \vdash t=$ $a: T$.
Proof. By the fundamental theorem, $\Gamma \vdash t \widehat{\widehat{S}} t: T$ which by definition contains a derivation of $\Gamma \vdash t=\downarrow t: T$.
5.5. Consistency. Importantly, not every type is inhabited in IITT, thus, it can be used as a logic. A prerequisite is that types can be distinguished, which follows immediately from the construction of the logical relation.
Lemma 5.10 (Type constructor discrimination). Neutral types, sorts and function types are mutually unequal.
(1) $\Gamma \vdash N \neq s$.
(2) $\Gamma \vdash N \neq(x \star U) \rightarrow T$.
(3) $\Gamma \vdash s=s^{\prime}$ implies $s \equiv s^{\prime}$.
(4) $\Gamma \vdash s \neq(x \star U) \rightarrow T$.

Proof. By the fundamental theorem applied to the identity substitution. For instance, assuming $\Gamma \vdash N=s: s^{\prime}$ we get $\Gamma \vdash N$ (S) $s: s^{\prime}$ but this is a contradiction to the definition of (S).

From normalization and type constructor discrimination we can show that not every type is inhabited.
Theorem 5.11 (Consistency). $X: \operatorname{Set}_{0} \nvdash t: X$.

Proof. Let $\Gamma=\left(X: \operatorname{Set}_{0}\right)$. Assuming $\Gamma \vdash t: X$, we have $\Gamma \vdash a: X$ for the whnf $a$ of $t$. We invert on the typing of $a$. By Lemma 5.10, $X$ cannot be equal to a function type or sort, thus, $a$ can neither be a $\lambda$ nor a function type nor a sort, it can only be neutral. The only variable $X$ must be in the head of $a$, but since $X$ is not of function type, it cannot be applied. Thus, $a \equiv X$ and $\Gamma \vdash X: X$, implying $\Gamma \vdash X=\operatorname{Set}_{0}$ by inversion (Lemma 5.5). This is in contradiction to Lemma 5.10.
5.6. Soundness of Algorithmic Equality. Soundness of the equality algorithm is a consequence of subject reduction.
Theorem 5.12 (Soundness of algorithmic equality).
(1) Let $\Delta \vdash t, t^{\prime}: T$. If $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$ then $\Delta \vdash t=t^{\prime}: T$.
(2) Let $\Delta \vdash n, n^{\prime}: T$. If $\Delta \vdash n \stackrel{\longleftrightarrow}{\longleftrightarrow} n^{\prime}: U$ then $\Delta \vdash n=n^{\prime}: U$ and $\Delta \vdash U=T$.

Proof. Generalize the theorem to all six algorithmic equality judgments and prove it by induction on the algorithmic equality derivation. Since we have subject reduction, the proof proceeds mechanically, because each algorithmic rule corresponds, modulo weak head normalization, to a declarative rule.
Case $\Delta \vdash T: s$ and $\Delta^{\prime} \vdash T^{\prime}: s$ and

$$
\frac{\Delta \vdash \downarrow T \Longleftrightarrow \downarrow T^{\prime}}{\Delta \vdash T \Longleftrightarrow T^{\prime}}
$$

By induction hypothesis, $\Delta \vdash \downarrow T=\downarrow T^{\prime}: s$. By subject reduction $\Delta \vdash T=\downarrow T: s$ and $\Delta \vdash T^{\prime}=\downarrow T^{\prime}: s$. By transitivity $\Delta \vdash T=T^{\prime}: s$.
Case

$$
\frac{\Delta \vdash T \Longleftrightarrow T^{\prime}}{\Delta \vdash T \Longleftrightarrow T^{\prime}: s}
$$

By induction hypothesis, $\Delta \vdash T=T^{\prime}: s$.
5.7. Symmetry and Transitivity of Algorithmic Equality. Since algorithmic equality is sound for well-typed terms, it is also symmetric and transitive.

Lemma 5.13 (Type and context conversion in algorithmic equality). Let $\vdash \Delta=\Delta^{\prime}$.
(1) If $\Delta \vdash A, A^{\prime}$ and $\Delta \vdash A \Longleftrightarrow A^{\prime}$ then $\Delta^{\prime} \vdash A \Longleftrightarrow A^{\prime}$.
(2) If $\Delta \vdash n, n^{\prime}: A$ and $\Delta \vdash n \longleftrightarrow n^{\prime}: A$ then $\Delta^{\prime} \vdash n \longleftrightarrow n^{\prime}: A^{\prime}$ for some $A^{\prime}$ with $\Delta \vdash A=A^{\prime}$.
(3) If $\Delta \vdash t, t^{\prime}: A$ and $\Delta \vdash t \Longleftrightarrow t^{\prime}: A$ and $\Delta \vdash A=A^{\prime}$ then $\Delta^{\prime} \vdash t \Longleftrightarrow t^{\prime}: A^{\prime}$.

Proof. By induction on the derivation of algorithmic equality, where we extend the statements to $\stackrel{\wedge}{\longleftrightarrow}$ and $\Longleftrightarrow$ accordingly.
(1) Type equality.

Case

$$
\frac{\Delta \vdash U \Longleftrightarrow U^{\prime} \quad \Delta . x \star U \vdash T \Longleftrightarrow T^{\prime}}{\Delta \vdash(x \star U) \rightarrow T \Longleftrightarrow\left(x \star U^{\prime}\right) \rightarrow T^{\prime}}
$$

By inversion, $\Delta \vdash U, U^{\prime}$ and by induction hypothesis, $\Delta^{\prime} \vdash U \Longleftrightarrow U^{\prime}$. Again by inversion, $\Delta . x \star U \vdash T$ and $\Delta . x \star U^{\prime} \vdash T^{\prime}$, yet by soundness of algorithmic equality, $\Delta \vdash U=U^{\prime}$, hence $\Delta . x \star U \vdash T^{\prime}$ by context conversion. Further, $\vdash \Delta . x \star U=$
$\Delta^{\prime} . x \star U$. Thus, we can apply the other induction hypothesis to obtain $\Delta^{\prime} . x \star U \vdash$ $T \Longleftrightarrow T^{\prime}$, which finally yields $\Delta^{\prime} \vdash(x \star U) \rightarrow T \Longleftrightarrow\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$.
(2) Structural equality.

Case

$$
\frac{(x: T) \in \Delta}{\Delta \vdash x \stackrel{ }{\longleftrightarrow} x: T}
$$

Since $\vdash \Delta=\Delta^{\prime}$, there is a unique $\left(x: T^{\prime}\right) \in \Delta^{\prime}$ with $\Delta \vdash T=T^{\prime}$. Hence, $\Delta^{\prime} \vdash x \longleftrightarrow x: T^{\prime}$.
Case
Type-directed equality.
Case $\Delta \vdash t, t^{\prime}: T$ and $\Delta \vdash T=T^{\prime}$ and

$$
\frac{T \searrow A \quad \Delta \vdash t \Longleftrightarrow t^{\prime}: A}{\Delta \vdash t \Longleftrightarrow t^{\prime}: T}
$$

By normalization, $T^{\prime} \searrow A^{\prime}$, and subject reduction $\Delta \vdash A=T=T^{\prime}=A^{\prime}$. Since by conversion, $\Delta \vdash t, t^{\prime}: A$, by induction hypothesis $\Delta^{\prime} \vdash t \Longleftrightarrow t^{\prime}: A^{\prime}$. Thus, $\Delta^{\prime} \vdash t \Longleftrightarrow t^{\prime}: T^{\prime}$.
Case $\quad \Delta \vdash(x \star U) \rightarrow T=A^{\prime}$ and

$$
\frac{\Delta . x \star U \vdash t^{\star} x \Longleftrightarrow t^{\prime \star} x: T}{\Delta \vdash t \Longleftrightarrow t^{\prime}:(x \star U) \rightarrow T}
$$

By injectivity $A^{\prime} \equiv\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$ with $\Delta \vdash U=U^{\prime}$ and $\Delta$. $x \star U \vdash T=T^{\prime}$. Since $\vdash \Delta . x \star U=\Delta^{\prime} . x \star U^{\prime}$, by induction hypothesis we have $\Delta^{\prime} . x \star U^{\prime} \vdash t^{\star} x \Longleftrightarrow t^{\prime \star} x$ : $T^{\prime}$. We conclude $\Delta^{\prime} \vdash t \Longleftrightarrow t^{\prime}:\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$.

Lemma 5.14 (Algorithmic equality is transitive). Let $\vdash \Delta=\Delta^{\prime}$. In the following, let the terms submitted to algorithmic equality be well-typed.
(1) If $\Delta \vdash n_{1} \longleftrightarrow n_{2}: T$ and $\Delta^{\prime} \vdash n_{2} \longleftrightarrow n_{3}: T^{\prime}$ then $\Delta \vdash n_{1} \longleftrightarrow n_{3}: T$ and $\Delta \vdash T=T^{\prime}$.
(2) If $\Delta \vdash t_{1} \Longleftrightarrow t_{2}: T$ and $\Delta^{\prime} \vdash t_{2} \Longleftrightarrow t_{3}: T^{\prime}$ and $\Delta \vdash T=T^{\prime}$ then $\Delta \vdash t_{1} \Longleftrightarrow t_{3}: T$.
(3) If $\Delta \vdash T_{1} \Longleftrightarrow T_{2}: s$ and $\Delta^{\prime} \vdash T_{2} \Longleftrightarrow T_{3}:$ s then $\Delta \vdash T_{1} \Longleftrightarrow T_{3}: s$

Proof. We extend these statements to $\longleftrightarrow$ and $\Longleftrightarrow$ and prove them simultaneously by induction on the first derivation.
Case

$$
\frac{\Delta \vdash n_{1} \longleftrightarrow n_{2}: T}{\Delta \vdash n_{1} \Longleftrightarrow n_{2}: N} \quad \frac{\Delta^{\prime} \vdash n_{2} \longleftrightarrow n_{3}: T^{\prime}}{\Delta^{\prime} \vdash n_{2} \Longleftrightarrow n_{3}: N^{\prime}}
$$

By induction hypothesis $\Delta \vdash n_{1} \longleftrightarrow n_{3}: T$, hence, $\Delta \vdash n_{1} \Longleftrightarrow n_{3}: N$.
Case

$$
\frac{\Delta \vdash N_{1} \longleftrightarrow N_{2}: T}{\Delta \vdash N_{1} \Longleftrightarrow N_{2}} \quad \frac{\Delta \vdash N_{2} \longleftrightarrow N_{3}: T^{\prime}}{\Delta \vdash N_{2} \Longleftrightarrow N_{3}}
$$

Analogously.

Case

$$
\begin{aligned}
& \frac{\Delta \vdash n_{1} \longleftrightarrow n_{2}:(x: U) \stackrel{s_{1}, s_{2}}{\longrightarrow} T \quad \Delta \vdash u_{1} \stackrel{ }{\longleftrightarrow} u_{2}: U}{\Delta \vdash n_{1} u_{1} \longleftrightarrow n_{2} u_{2}: T\left[u_{1} / x\right]} \\
& \frac{\Delta^{\prime} \vdash n_{2} \longleftrightarrow n_{3}:\left(x: U^{\prime}\right) \stackrel{s_{1}^{\prime}, s_{2}^{\prime}}{\longleftrightarrow} T^{\prime} \quad \Delta^{\prime} \vdash u_{2} \widehat{\longleftrightarrow} u_{3}: U^{\prime}}{\Delta^{\prime} \vdash n_{2} u_{2} \overleftrightarrow{\longleftrightarrow} n_{3} u_{3}: T^{\prime}\left[u_{2} / x\right]}
\end{aligned}
$$

By induction hypothesis we have $\Delta \vdash n_{1} \longleftrightarrow n_{3}:(x: U) \xrightarrow{s_{1}, s_{2}} T$ and $\Delta \vdash(x: U) \xrightarrow{s_{1}, s_{2}}$ $T=\left(x: U^{\prime}\right) \xrightarrow{s_{1}^{\prime}, s_{2}^{\prime}} T^{\prime}$ which gives in particular $s_{1}=s_{1}^{\prime}, s_{2}=s_{2}^{\prime}$, and $\Delta \vdash U=U^{\prime}: s_{1}$ by function type injectivity (Thm. 5.7). By induction hypothesis we can then deduce $\Delta \vdash u_{1} \Longleftrightarrow u_{3}: U$, and therefore conclude $\Delta \vdash n_{1} u_{1} \longleftrightarrow n_{3} u_{3}: T\left[u_{1} / x\right]$.
Case

$$
\begin{aligned}
& \frac{\Delta \vdash U_{2} \Longleftrightarrow U_{3}: s_{1} \quad \Delta \cdot x \star U_{2} \vdash T_{2} \Longleftrightarrow T_{3}: s_{2}}{\Delta \vdash\left(x \star U_{2}\right) \xrightarrow{s_{1}, s_{2}} T_{2} \Longleftrightarrow\left(x \star U_{3}\right) \xrightarrow{s_{1}, s_{2}} T_{3}: s_{2}}
\end{aligned}
$$

We get $\Delta \vdash U_{1} \Longleftrightarrow U_{3}: s_{1}$ by transitivity. To also get $\Delta$. $x \star U_{1} \vdash T_{1} \Longleftrightarrow T_{3}: s_{2}$ we need $\vdash \Delta . x \star U_{2}=\Delta . x \star U_{1}$, but this stems from $\Delta \vdash U_{1} \Longleftrightarrow U_{2}: s_{1}$ by soundness of algorithmic equality.
Theorem 5.15. The algorithmic equality relations are PERs on well-typed expressions.
Proof. By Lemma 5.14 and an analogous proof of symmetry.

## 6. A Kripke Logical Relation for Completeness

The only open issues in the meta-theory of IITT are completeness and termination of algorithmic equality. In parts, completeness has been established in the last section already, namely, we have shown injectivity and discrimination for type constructors. What is missing is injectivity and discrimination for neutrals, e. g., if $\Delta \vdash n u=n^{\prime} u^{\prime}: T^{\prime}$ then necessarily $\Delta \vdash n=n^{\prime}:(x: U) \rightarrow T$ and $\Delta \vdash u=u^{\prime}: U$, plus $\Delta \vdash T[u / x]=T^{\prime}$. In untyped $\lambda$ calculus, this is an instance of Boehm's theorem Bar84. We follow Coquand Coq91 and Harper and Pfenning [HP05 and prove it by constructing a second Kripke logical relation, © , for completeness which is very similar to the first one, (S), but at base types additionally requires algorithmic equality to hold. After proving the fundamental lemma again, we know that definitionally equal terms are also algorithmically so. As a consequence, equality is decidable in IITT, and so is type checking.
6.1. Another Kripke Logical Relation. Again, by induction on $A \in s$ we define two Kripke relations

$$
\begin{gathered}
\Delta \vdash A \text { © } A^{\prime}: s \\
\Delta \vdash a \text { © } a^{\prime}: A .
\end{gathered}
$$

together with their respective closures $\widehat{C}$ and the generalization to $\star$. This time, however, at base types we will additionally require algorithmic equality to hold, more precisely, the relation $\Delta \vdash t: \Longleftrightarrow: t^{\prime}: T$ which stands for the conjunction of the propositions

- $\Delta \vdash t: T$ and $\Delta \vdash t^{\prime}: T$, and
- $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$.

Note that by soundness of algorithmic equality, $: \Longleftrightarrow$ : implies $:=:$.
Again, we allow ourselves rule notation for the defining clauses of (c).

$$
\begin{aligned}
& \frac{\Delta \vdash N: \Longleftrightarrow: N^{\prime}: s}{\Delta \vdash N\left(N^{\prime}: s\right.} \quad \frac{\Delta \vdash n: \Longleftrightarrow: n^{\prime}: N}{\Delta \vdash n \text { © } n^{\prime}: N} \quad \frac{\vdash \Delta}{\Delta \vdash s \text { © } s: s^{\prime}}\left(s, s^{\prime}\right) \\
& \Delta \vdash U \widehat{(C)} U^{\prime}: s_{1} \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{\complement} u^{\prime} \star U \Longrightarrow \Gamma \vdash T[u / x] \widehat{\text { © }} T^{\prime}\left[u^{\prime} / x\right]: s_{2} \\
& \frac{\Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T:=:\left(x \star U^{\prime}\right) \xrightarrow{s_{1}, s_{2}} T^{\prime}: s_{3}}{\Delta \vdash(x \star U) \xrightarrow{s_{1}, s_{2}} T \text { © }\left(x \star U^{\prime}\right) \xrightarrow{s_{1}, s_{2}} T^{\prime}: s_{3}}\left(s_{1}, s_{2}, s_{3}\right) \\
& \forall \Gamma \leq \Delta, \Gamma \vdash u \widehat{(c)} u^{\prime} \star U \Longrightarrow \Gamma \vdash f^{\star} u \widehat{(C)} f^{\prime \star} u^{\prime}: T[u / x] \\
& \frac{\Delta \vdash f:=: f^{\prime}:(x \star U) \xrightarrow{s, s^{\prime}} T}{\Delta \vdash f(c) f^{\prime}:(x \star U) \xrightarrow{s, s^{\prime}} T} \\
& \frac{\Delta \vdash \downarrow t \text { © } \downarrow t^{\prime}: \downarrow T \quad \Delta \vdash t:=: t^{\prime}: T}{\Delta \vdash t \widehat{\text { © } t^{\prime}: T}} \\
& \frac{\Delta^{\div} \vdash a \text { (c) } a: A \quad \Delta^{\div} \vdash a^{\prime} \text { (c) } a^{\prime}: A}{\Delta \vdash a \text { (c) } a^{\prime} \div A} \quad \frac{\Delta^{\div} \vdash t \widehat{\text { © } t: T} \quad \Delta^{\div} \vdash t^{\prime} \widehat{\text { © } t^{\prime}: T}}{\Delta \vdash t \widehat{\text { © }} t^{\prime} \div T}
\end{aligned}
$$

This logical relation contains only well-typed and definitionally equal terms. It is symmetric, transitive, and closed under weakening and type conversion. The proofs are in analogy to those of Section 4, which are relying on the fact that the underlying relation $:=$ : is a Kripke PER and closed under type conversion. The relation $: \Longleftrightarrow$ : underlying © has the same properties, thanks to soundness of algorithmic equality.

Note that in the definition of $\Delta \vdash f$ © $f^{\prime}:(x \star U) \rightarrow T$ we did not require $f$ and $f^{\prime}$ to be algorithmically equal. This would hinder the proof of the fundamental theorem for (c), since algorithmic equality is not closed under application by definition-it will follow from the fundamental theorem, though. In the next lemma we shall prove that $f$ and $f^{\prime}$ are algorithmically equal if they are related by ©. The name Escape Lemma was coined by Jeffrey Sarnat [SS08].

Lemma 6.1 (Escape from the logical relation). Let $\Delta \vdash A$ (c) $A^{\prime}: s$
(1) $\Delta \vdash A \Longleftrightarrow A^{\prime}$.
(2) If $\Delta \vdash t \widehat{(C)} t^{\prime}: A$ then $\Delta \vdash t \Longleftrightarrow t^{\prime}: A$.
(3) If $\Delta \vdash n \longleftrightarrow n^{\prime} \star A$ and $\Delta \vdash n=n^{\prime} \star A$ then $\Delta \vdash n$ © $n^{\prime} \star A$.

Corollary 6.2. Let $\Delta \vdash T \widehat{(C)} T^{\prime}: s$
(1) $\Delta \vdash T \Longleftrightarrow T^{\prime}$.
(2) If $\Delta \vdash t \widehat{(C)} t^{\prime}: T$ then $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$.
(3) If $\Delta \vdash n \stackrel{\longleftrightarrow}{\longleftrightarrow} n^{\prime} \star T$ and $\Delta \vdash n=n^{\prime} \star T$ then $\Delta \vdash n \widehat{(\bigodot} n^{\prime} \star T$.

The corollary is a direct, non-inductive consequence of the lemma, so we can use it in the proof of the lemma, quoted as "IH".
Proof of the lemma. Simultaneously by induction on $A: \Longleftrightarrow: A^{\prime}: s$.
Case $\Delta \vdash N$ © $N^{\prime}: s$.
Case $1 . \Delta \vdash N \Longleftrightarrow N^{\prime}$ by assumption.
Case 2. We have $\Delta \vdash \downarrow t \longleftrightarrow \downarrow t^{\prime}:{ }_{-}$, thus $\Delta \vdash t \Longleftrightarrow t^{\prime}: N$.
Case 3 .
First, consider $\star=:$. If $\Delta \vdash n=n^{\prime}: N$ and $\Delta \vdash n \longleftrightarrow n^{\prime}: N$ then $\Delta \vdash n \Longleftrightarrow n^{\prime}: N$ and trivially $\Delta \vdash n$ © $n^{\prime}: N$.
Then, take $\star=\div$. Note that if $\Delta \div \vdash n=n: N$ and $\Delta \div \vdash n \longleftrightarrow n: N$ then $\Delta \div \vdash n \Longleftrightarrow n: N$ and $\Delta^{\div} \vdash n$ (c) $n: N$. This implies that if $\Delta \vdash n=n^{\prime} \div N$ and $\Delta \vdash n \longleftrightarrow n^{\prime} \div N$ then $\Delta \vdash n \Longleftrightarrow n^{\prime} \div N$ and $\Delta \vdash n$ © $n^{\prime} \div N$.
Case $\Delta \vdash s$ © $s: s^{\prime}$.
Case 11. Clearly, $\Delta \vdash s \Longleftrightarrow s$.
Case 2. Let $\Delta \vdash T \widehat{(c)} T^{\prime}: s$. Then $\Delta \vdash T \Longleftrightarrow T^{\prime}$ by IH ${ }^{1}$ thus $\Delta \vdash T \Longleftrightarrow T^{\prime}: s$
Case 3. For $\star=:$ let $\Delta \vdash N \longleftrightarrow N^{\prime}: s$. By inversion, $\Delta \vdash N \longleftrightarrow N^{\prime}: T$ for some $T$.
Then $\Delta \vdash N \Longleftrightarrow N^{\prime}$ and $\Delta \vdash N$ © $N^{\prime}: s$ by definition.
Considering $\star=\div$, it is sufficient to observe that $\Delta^{\div} \vdash N \longleftrightarrow N: s$ implies $\Delta^{\div} \vdash N \Longleftrightarrow N$ and $\Delta^{\div} \vdash N$ © $N: s$ by definition.
Case $\quad \Delta \vdash(x \star U) \rightarrow T$ © $\left(x \star U^{\prime}\right) \rightarrow T^{\prime}: s_{3}$.
Case 1. Similar to 2 .
Case 2. By assumption, $\Delta \vdash t \widehat{(C)} t^{\prime}:(x \star U) \rightarrow T$. It is sufficient to show $\Delta$. $x \star U \vdash$ $t^{\star} x \Longleftrightarrow t^{\prime *} x: T$. Since $\Delta \vdash U \widehat{C} U^{\prime}: s_{1}$, which includes $\Delta \vdash U$, we have $\Delta . x \star U \vdash$ $x=x \star U$. Since also $\Delta . x \star U \vdash x \longleftrightarrow \longleftrightarrow x \star U$, we obtain $\Delta . x \star U \vdash t^{\star} x \widehat{\complement} t^{\prime \star} x: \downarrow T$ via IH 3, $\Delta . x \star U \vdash x$ © $x \star U$. IH 2 then entails our goal.
Case 3. First, the case for $\star=:$. We reuse variable $\star$ for a different irrelevance marker. We have $\Delta \vdash n \longleftrightarrow n^{\prime}:(x \star U) \rightarrow T$. Assume arbitrary $\Gamma: \Longleftrightarrow: \Gamma \leq \Delta$ and $\Gamma \vdash u \widehat{C} u^{\prime} \star U$, which yields $\Gamma \vdash u=u^{\prime} \star U$ and $\Gamma \vdash T[u / x] \widehat{\text { © }} T\left[u^{\prime} / x\right]: \operatorname{Set}_{i}$. In case $\star=$ : we have to apply IH 2 for $\Gamma \vdash u \Longleftrightarrow u^{\prime}: \downarrow U$. Otherwise, we obtain directly $\Gamma \vdash n^{\star} u \longleftrightarrow n^{\prime *} u^{\prime}: \downarrow(T[u / x])$. By IH 3, $\Gamma \vdash n^{\star} u$ © $n^{\prime \star} u^{\prime}: \downarrow(T[u / x])$.
The case for $\star=\div$ proceeds analogously.
In analogy to $\widehat{\text { © }}$ we extend $\widehat{〔}$ to substitutions and define the semantic validity judgements $\Vdash^{\mathrm{c}} \Gamma$ and $\Gamma \Vdash^{\mathrm{c}} t: T$ and $\Gamma \Vdash^{\mathrm{c}} t=t^{\prime}: T$ based on © $\widehat{C}$. Since by the escape lemma, $\Delta \vdash x$ © $x: \Delta(x)$, we have $\Gamma \vdash$ id $\widehat{\text { © }}$ id $: \Gamma$ for $\Vdash^{\mathrm{c}} \Gamma$. Finally, we reprove the fundamental theorem:

Theorem 6.3 (Fundamental theorem for © $\widehat{\text { © }) . ~}$
(1) If $\vdash \Gamma$ then $\Vdash^{\mathrm{c}} \Gamma$.
(2) If $\Gamma \vdash t: T$ then $\Gamma \Vdash^{\mathrm{c}} t: T$.
(3) If $\Gamma \vdash t=t^{\prime}: T$ then $\Gamma \Vdash^{\mathrm{c}} t=t^{\prime}: T$.
6.2. Completeness and Decidability of Algorithmic Equality. Derivations of algorithmic equality can now be obtained by escaping from the logical relation.

Theorem 6.4 (Completeness of algorithmic equality). $\Gamma \vdash t=t^{\prime}: T$ implies $\Gamma \vdash t \Longleftrightarrow$ $t^{\prime}: T$.

Proof. Since $\Gamma \vdash$ id $\widehat{\text { c }}$ id $: \Gamma$, we have $\Gamma \vdash t \widehat{\text { © }} t^{\prime}: T$ by the fundamental theorem, and conclude with Lemma 6.12.

Termination of algorithmic equality is a consequence of completeness. When invoking the algorithmic equality check $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$ on two well-typed expressions $\Delta \vdash t, t^{\prime}: T$ we know by completeness that $t$ and $t^{\prime}$ are related to themselves, i. e., $\Delta \vdash t \Longleftrightarrow t: T$ and $\Delta \vdash t^{\prime} \Longleftrightarrow t^{\prime}: T$. This means that $t, t^{\prime}$, and $T$ are weakly normalizing by the strategy the equality algorithm implements: reduce to weak head normal form and recursively continue with the subterms. Running the equality check on $t$ and $t^{\prime}$ performs, if successful, exactly the same reductions, and if it fails, at most the same reductions in $t, t^{\prime}$, and $T$. Hence, testing equality on well-typed terms always terminates. This argument has been applied in previous work to untyped equality AC07. Here, we apply it to typed equality; it is an alternative to Goguen's technique of proving termination for typed equality from strong normalization Gog05, which, in our opinion, does not scale to dependently-typed equality.

Lemma 6.5 (Termination of algorithmic equality). Let $\vdash \Delta$.
(1) Type equality.
(a) Let $\Delta \vdash A, A^{\prime}$. If $\mathcal{D}:: \Delta \vdash A \Longleftrightarrow A$ and $\Delta \vdash A^{\prime} \Longleftrightarrow A^{\prime}$ then the query $\Delta \vdash A \Longleftrightarrow A^{\prime}$ terminates
(b) Let $\Delta \vdash T, T^{\prime}$. If $\mathcal{D}:: \Delta \vdash T \Longleftrightarrow ~ \Longleftrightarrow ~ a n d ~ \Delta \vdash T^{\prime} \Longleftrightarrow T^{\prime}$ then the query $\Delta \vdash T \Longleftrightarrow$ $T^{\prime}$ terminates.
(2) Structural equality. Let $\Delta \vdash n: T$ and $\Delta \vdash n^{\prime}: T^{\prime}$.
(a) If $\mathcal{D}:: \Delta \vdash n \longleftrightarrow n: A$ and $\Delta \vdash n^{\prime} \longleftrightarrow n^{\prime}: A^{\prime}$ then the query $\Delta \vdash n \longleftrightarrow n^{\prime}:$ ? terminates. If successfully, it returns $A$ and we have $\Delta \vdash A=T=T^{\prime}=A$.
(b) If $\mathcal{D}:: \Delta \vdash n \longleftrightarrow n: T$ and $\Delta \vdash n^{\prime} \longleftrightarrow n^{\prime}: T^{\prime}$ then the query $\Delta \vdash n \overleftrightarrow{\longleftrightarrow} n^{\prime}:$ ? terminates. If successfully, it returns $T$ and we have $\Delta \vdash T=T^{\prime}$.
(3) Type-directed equality.
(a) Let $\Delta \vdash t, t^{\prime}: A$. If $\mathcal{D}:: \Delta \vdash t \Longleftrightarrow t: A$ and $\Delta \vdash t^{\prime} \Longleftrightarrow t^{\prime}: A$ then the query $\Delta \vdash t \Longleftrightarrow t^{\prime}: A$ terminates.
(b) Let $\Delta \vdash t, t^{\prime}: T$. If $\mathcal{D}:: \Delta \vdash t \stackrel{\Longleftrightarrow}{\Longleftrightarrow}: T$ and $\Delta \vdash t^{\prime} \Longleftrightarrow t^{\prime}: T$ then the query $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$ terminates.

Proof. Simultaneously by induction on derivation $\mathcal{D}$.
(1) Type equality.

Case $A=A^{\prime}=s$. The query $\Delta \vdash A \Longleftrightarrow A^{\prime}$ terminates successfully.
Case $A=(x \star U) \rightarrow T$ and $A^{\prime}=\left(x \star U^{\prime}\right) \rightarrow T^{\prime}$. First, the query $\Delta \vdash U \Longleftrightarrow U^{\prime}$ runs. By induction hypothesis, it terminates. If it fails, the whole query fails. Otherwise, the query $\Delta . x \star U \vdash T \Longleftrightarrow T^{\prime}$ is run. By induction hypothesis on $\Delta$. $x \star U \vdash T \Longleftrightarrow ~ Һ T$ and $\Delta$. $x \star U^{\prime} \vdash T^{\prime} \Longleftrightarrow T^{\prime}$, the query terminates.
Case $A=N$ and $A^{\prime}=N^{\prime}$ neutral. By induction hypothesis on $\Delta \vdash N \longleftrightarrow N: T$ and $\Delta \vdash N^{\prime} \longleftrightarrow N^{\prime}: T^{\prime}$, the query $\Delta \vdash N \longleftrightarrow N^{\prime}:$ ? terminates. Hence, the query $\Delta \vdash N \Longleftrightarrow N^{\prime}$ terminates.

Case Weak head normal forms $A, A^{\prime}$ not covered by previous cases: the query $\Delta \vdash$ $A \Longleftrightarrow A^{\prime}$ fails immediately, since there is no applicable algorithmic type equality rule.
Case The query $\Delta \vdash T \Longleftrightarrow T^{\prime}$ first invokes weak head normalization on $T$ and $T^{\prime}$. Both terminate since $\Delta \vdash T \Longleftrightarrow T$, which implies $T \searrow A$, and analogously $T^{\prime} \searrow A^{\prime}$ since $\Delta \vdash T^{\prime} \Longleftrightarrow T^{\prime}$ by assumption. Then, the query $\Delta \vdash A \Longleftrightarrow A^{\prime}$ is run, which terminates by induction hypothesis on $\Delta \vdash A \Longleftrightarrow A$ and $\Delta \vdash A^{\prime} \Longleftrightarrow A^{\prime}$.
(2) Structural equality.

Case $n=n^{\prime}=x$. The query $\Delta \vdash n \stackrel{\hookrightarrow}{\longleftrightarrow} n^{\prime}$ : ? terminates successfully, returning type $\Delta(x)$. Since $\vdash \Delta$, by inversion (Lemma 5.5) $\Delta \vdash T=T^{\prime}=\Delta(x)$.
Case Neutral relevant application for $\Delta \vdash n u: T_{0}$ and $\Delta \vdash n^{\prime} u^{\prime}: T_{0}^{\prime}$.

$$
\begin{aligned}
& \frac{\Delta \vdash n \longleftrightarrow n:(x: U) \rightarrow T \quad \Delta \vdash u \stackrel{\longleftrightarrow}{\Longleftrightarrow} u: U}{\Delta \vdash n u \longleftrightarrow n u: T[u / x]} \\
& \frac{\Delta \vdash n^{\prime} \longleftrightarrow n^{\prime}:\left(x: U^{\prime}\right) \rightarrow T^{\prime} \quad \Delta \vdash u^{\prime}}{\Delta \vdash n^{\prime} u^{\prime} \longleftrightarrow n^{\prime} u^{\prime}: T^{\prime}\left[u^{\prime} / x\right]}
\end{aligned}
$$

The query $\Delta \vdash n u \longleftrightarrow n^{\prime} u^{\prime}:$ ? first invokes query $\Delta \vdash n \longleftrightarrow n^{\prime}:$ ?. By induction hypothesis on $\Delta \vdash n \longleftrightarrow n:(x: U) \rightarrow T$ and $\Delta \vdash n^{\prime} \longleftrightarrow n^{\prime}:\left(x: U^{\prime}\right) \rightarrow T^{\prime}$ the query terminates. If it fails the whole query fails. Otherwise it returns a type $A$ in weak head normal form, which is identical to $(x: U) \rightarrow T$ by uniqueness of inferred types (Lemma 3.1). Further, $\Delta \vdash(x: U) \rightarrow T=\left(x: U^{\prime}\right) \rightarrow T^{\prime}$, and by function type injectivity (Thm. 5.7), $\Delta \vdash U=U^{\prime}$ and $\Delta . x: U \vdash T=T^{\prime}$. Thus, we can invoke the induction hypothesis on $\Delta \vdash u \Longleftrightarrow u: U$ and $\Delta \vdash u^{\prime} \Longleftrightarrow u^{\prime}: U$ (cast from $\Delta \vdash u^{\prime} \Longleftrightarrow u^{\prime}: U^{\prime}$, Lemma 5.13) to infer that the second subquery $\Delta \vdash u \Longleftrightarrow u^{\prime}: U$ terminates. If this one is successful, then by soundness of algorithmic equality, $\Delta \vdash u=u^{\prime}: U$, which implies $\Delta \vdash T[u / x]=T^{\prime}\left[u^{\prime} / x\right]$.
Case Neutral irrelevant application with typing
$\frac{\Delta \vdash n:\left(x \div U_{1}\right) \rightarrow T_{1} \quad \Delta \vdash u \div U_{1}}{\Delta \vdash n \div u: T_{1}[u / x]} \quad \frac{\Delta \vdash n^{\prime}:\left(x \div U_{1}^{\prime}\right) \rightarrow T_{1}^{\prime} \quad \Delta \vdash u^{\prime} \div U_{1}^{\prime}}{\Delta \vdash n^{\prime} \div u^{\prime}: T_{1}^{\prime}\left[u^{\prime} / x\right]}$
and algorithmic self-equality

$$
\frac{\Delta \vdash n \longleftrightarrow n:(x \div U) \rightarrow T}{\Delta \vdash n \div u \overleftrightarrow{\longleftrightarrow} \div \cdot u: T[u / x]} \quad \frac{\Delta \vdash n^{\prime} \longleftrightarrow n^{\prime}:\left(x \div U^{\prime}\right) \rightarrow T^{\prime}}{\Delta \vdash n^{\prime} \div u^{\prime} \overleftrightarrow{\longleftrightarrow} n^{\prime} \div u^{\prime}: T^{\prime}\left[u^{\prime} / x\right]}
$$

The query $\Delta \vdash n \div u \longleftrightarrow n^{\prime} \div u^{\prime}:$ ? invokes query $\Delta \vdash n \longleftrightarrow n^{\prime}:$ ?, which terminates by induction hypothesis. If successfully, then $\Delta \vdash\left(x \div U_{1}\right) \rightarrow T_{1}(x \div U) \rightarrow T=$ $\left(x \div U^{\prime}\right) \rightarrow T^{\prime}=\left(x \div U_{1}^{\prime}\right) \rightarrow T_{1}^{\prime}$. By function type injectivity, $\Delta \vdash U_{1}=U=U^{\prime}=U_{1}^{\prime}$ and $\Delta$. $x \div U \vdash T_{1}=T=T^{\prime}=T_{1}^{\prime}$. By conversion $\Delta \vdash u=u^{\prime} \div U$, thus, $\Delta \vdash$ $T_{1}[u / x]=T[u / x]=T^{\prime}\left[u^{\prime} / x\right]=T_{1}^{\prime}\left[u^{\prime} / x\right]$.
Case In all other cases, the query $\Delta \vdash n \longleftrightarrow n^{\prime}$ : ? fails immediately.
Case The query $\Delta \vdash n \longleftrightarrow n:$ ? spawns subquery $\Delta \vdash n \longleftrightarrow n^{\prime}$ : ? which terminates by induction hypothesis on $\Delta \vdash n \stackrel{\wedge}{\longleftrightarrow} n: T$ and $\Delta \vdash n^{\prime} \stackrel{\wedge}{\longleftrightarrow} n^{\prime}: T^{\prime}$. If successfully, it returns type $T$, and since $T \searrow A$, the original query also terminates, returning $A$.
(3) Type-directed equality.

Case Function type $\Delta \vdash t, t^{\prime}:(x \star U) \rightarrow T$. The query $\Delta \vdash t \Longleftrightarrow t^{\prime}:(x \star U) \rightarrow T$ spawns subquery $\Delta . x \star U \vdash t^{\star} x \Longleftrightarrow t^{\prime \star}: T$. Since $\Delta . x \star U \vdash t^{\star} x, t^{\prime \star} x: T$ and the
subquery terminates by induction hypothesis on $\Delta$ ．$x \star U \vdash t^{\star} x \Longleftrightarrow t^{\star} x: T$ and $\Delta . x \star U \vdash t^{\prime \star} x \Longleftrightarrow t^{\prime \star} x: T$ ．
Case Sort $\Delta \vdash T, T^{\prime}: s$ ．The query $\Delta \vdash T \Longleftrightarrow T^{\prime}: s$ calls $\Delta \vdash T \Longleftrightarrow T^{\prime}$ ，which terminates by induction hypothesis on $\Delta \vdash T \Longleftrightarrow T$ and $\Delta \vdash T^{\prime} \Longleftrightarrow T^{\prime}$ ．
Case Neutral type $N$ ．

$$
\frac{t \searrow n \quad \Delta \vdash n \stackrel{\hookrightarrow}{\longleftrightarrow} n: T}{\Delta \vdash t \Longleftrightarrow t: N} \quad \frac{t^{\prime} \searrow n^{\prime} \quad \Delta \vdash n^{\prime} \longleftrightarrow}{\Delta \vdash n^{\prime}: T^{\prime}} ⿻ 土 一 t^{\prime} \Longleftrightarrow t^{\prime}: N
$$

The query $\Delta \vdash t \Longleftrightarrow t^{\prime}: N$ first weak head normalizes $t$ and $t^{\prime}$ ．By assumption， $t \searrow n$ and $t^{\prime} \searrow n^{\prime}$ ，so this terminates．The subquery $\Delta \vdash n \overleftrightarrow{\longleftrightarrow} n^{\prime}:$ ？terminates by induction hypothesis．Thus，the whole query terminates．
Case If $A$ is neither a function type，a sort，or a neutral type，the query $\Delta \vdash t \Longleftrightarrow t^{\prime}: A$ fails immediately．
Case The query $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$ first weak head normalizes $T$ which terminates since $T \searrow A$ by assumption．Then it calls $\Delta \vdash t \Longleftrightarrow t^{\prime}: A$ which terminates by induction hypothesis．

Theorem 6．6．If $\Delta \vdash t: T$ and $\Delta \vdash t^{\prime}: T$ then the query $\Delta \vdash t \Longleftrightarrow t^{\prime}: T$ terminates．
Proof．From the lemma by completeness of algorithmic equality．
Thus we have shown that algorithmic equality is correct，i．e．，sound，complete，and terminating．Together，this entails decidability of equality in IITT．

Theorem 6.7 （Decidability of IITT）．
（1）$\Gamma \vdash t=t^{\prime}: T$ is decidable．
（2）$\Gamma \vdash t: T$ is decidable．
Proof．Decidability of equality follows from soundness（Thm．5．12），completeness（Thm．6．4）， and termination（Thm．6．6）．Decidability of typing follows from decidability of type conver－ sion，weak head normalization，and function type injectivity，using inversion（Lemma 5．5） on typing derivations．Any reasonable type inference algorithm will do．

## 7．Extensions

Data types and recursion．The semantics of IITT is ready to cope with inductive data types like the natural numbers and the associated recursion principles．Recursion into types，aka known as large elimination，is also accounted for since we have universes and a semantics which does not erase dependencies（unlike Pfenning＇s model［Pfe01）．

Types with extensionality principles．One purpose of having a typed equality algorithm is to handle $\eta$－laws that are not connected to the shape of the expression（like $\eta$－contraction for functions）but to the shape of the type only．Typically these are types $T$ with at most one inhabitant，i．e．，the empty type，the unit type，singleton types or propositions $\sqrt{6}$ For such $T$ we have the $\eta$－law

$$
\frac{\Gamma \vdash t, t^{\prime}: T}{\Gamma \vdash t=t^{\prime}: T}
$$

[^6]which can only be checked in the presence of type $T$. Realizing such $\eta$-laws gives additional "proof" irrelevance which is not covered by Pfenning's irrelevant quantification $(x \div U) \rightarrow T$.

Internal erasure. Terms $u \div U$ in irrelevant position are only there to please the type checker, they are ignored during equality checking. This can be inferred from the substitution principle: If $\Gamma . x \div U \vdash T$ and $\Gamma \vdash u, u^{\prime} \div U$, then $\Gamma \vdash T[u / x]=T\left[u^{\prime} / x\right]$; the type $T$ has the same shape regardless of $u, u^{\prime}$. Hence, terms like $u$ serve the sole purpose to prove some proposition and could be replaced by a dummy • immediately after type-checking.

Internal erasure can be realized by making $\Gamma \vdash t \div T$ a judgement (as opposed to just a notation for $\left.\Gamma^{\doteqdot} \vdash t: T\right)$ and adding the rule

$$
\frac{\Gamma \vdash t \div T}{\Gamma \vdash \bullet \div T}
$$

The rule states that if there is already a proof $t$ of $T$, then $\bullet$ is a new proof of $T$. This preserves provability while erasing the proof terms. Conservativity of this rule can be proven as in joint work of the author with Coquand and Pagano [ACP11.

## 8. Conclusions

We have extended Pfenning's notion of irrelevance to a type theory IITT with universes that accommodates types defined by recursion. We have constructed a Kripke model (S) that shows soundness of IITT, yielding normalization, subject reduction and consistency, plus syntactical properties of the judgements of IITT. A second Kripke logical relation © has proven correctness of algorithmic equality and, thus, decidability of IITT.

Integrating irrelevance and data types in dependent type theory does not seem without challenges. We have succeeded to treat Pfenning's notion of irrelevance, but our proof does not scale directly to parametric function types, a stronger notion of irrelevant function types called implicit quantification by Miquel Miq01b Two more type theories build on Miquel's calculus Miq01a, Barras and Bernardo's ICC* BB08] and Mishra-Linger and Sheard's Erasure Pure Type Systems (EPTS) MLS08, but none has offered a satisfying account of large eliminations yet. Miquel's model Miq00 features data types only as impredicative encodings. For irrelevant, parametric, and recursive functions to coexist it seems like three different function types are necessary, e.g., in the style of Pfenning's irrelevance, extensionality and intensionality. We would like to solve this puzzle in future work, not least to implement high-performance languages with dependent types.

Acknowledgments. The first author thanks Bruno Barras, Bruno Bernardo, Thierry Coquand, Dan Doel, Hugo Herbelin, Conor McBride, Ulf Norell, and Jason Reed for discussions on irrelevance in type theory. Work on a previous paper has been carried out while he was invited researcher at PPS, Paris, in the INRIA $\pi r^{2}$ team headed by Pierre-Louis Curien and Hugo Herbelin. The second author acknowledges financial support by the École Normale Superiéure de Paris for his internship at the Ludwig-Maximilians-Universität München from May to September 2011. We thank the two anonymous referees, who suggested changes and examples which significantly improved the presentation, and the patience of the editors waiting for our revisions.

[^8]
[^0]:    1998 ACM Subject Classification: F.4.1.
    Key words and phrases: dependent types, proof irrelevance, typed algorithm equality, logical relation, universal Kripke model.

    * Revision and extension of FoSSaCS 2011 conference publication.

[^1]:    ${ }^{1}$ Awodey and Bauer AB04 give a categorical treatment of proof irrelevance which is very similar to Pfenning and Reed's. However, they work in the setting of Extensional Type Theory with undecidable type checking, we could not directly use their results for this work.

[^2]:    ${ }^{2}$ This is why Reed Ree02 differs from Pfenning.

[^3]:    ${ }^{3}$ Example suggested by a reviewer of this paper.

[^4]:    ${ }^{4}$ Example suggested by reviewer.

[^5]:    ${ }^{5}$ Inspired by discussions with Ulf Norell during the 11th Agda Implementers' Meeting.

[^6]:    ${ }^{6}$ Some care is necessary for the type of Leibniz equality Abe09，Wer08．

[^7]:    ${ }^{7} \mathrm{~A}$ function argument is parametric if it is irrelevant for computing the function result while the type of the result may depend on it. In Pfenning's notion, the argument must also be irrelevant in the type.
