\textbf{Abstract.} We study operations on fixpoint equation systems (FES) over arbitrary complete lattices. We investigate under which conditions these operations, such as substituting variables by their definition, and swapping the ordering of equations, preserve the solution of a FES. We provide rigorous, computer-checked proofs. Along the way, we list a number of known and new identities and inequalities on extremal fixpoints in complete lattices.

\section{Introduction}

This paper deals with operations on systems of fixpoint equations over an arbitrary complete lattice. We investigate when these operations preserve the solution of the equations. An example of a system of equations is the set $E := \{X = f(X,Y,Z), Y = g(X,Y,Z), Z = h(X,Y,Z)\}$. For most results, it is required that the functions $f, g, h$ are monotonic in the given lattice. Such systems may well have multiple solutions. In order to specify particular solutions, we introduce specifications, for example $S := [\mu X, \nu Y, \mu Z]$, indicating for each variable whether we are interested in the minimal ($\mu$) or maximal ($\nu$) solution. The order of the variables in these specifications is relevant: the leftmost variable indicates the fixpoint with the highest priority. A Fixpoint Equation System (FES) \cite{Mad97} is a pair $(E, S)$, where $E$ is a set of equations, and $S$ is a specification. Several well known instances are obtained by instantiating the complete lattice.

\textbf{Well-known instances of FES.} Boolean Equation Systems (BES) arise as FES over the complete lattice $\bot < \top$, and were proposed in \cite{And94, AV95} for solving the model checking and equivalence checking problems on finite labeled transition systems (LTS). BES received extensive study in \cite{Mad97, MS03, GK04, Mat06}. A generalisation to the domain $\mathbb{R} \cup \{-\infty, \infty\}$ is real equation systems (RES) \cite{GW23}.

An equivalent notion to BES is two-player parity games \cite{EJ91}, see \cite{Mad97} for a proof. Algorithms for solving parity games receive a lot of attention, since this is one of the few problems which is in NP and in co-NP, but not known to be in P. Recently, it has been shown that parity games (and thus BES) can be solved in quasi-polynomial time \cite{CJK+17}. This result has also been lifted to the general setting of FES on finite lattices \cite{HS21, JMT22}.

\textit{Key words and phrases:} fixpoint equation system, complete lattice.
Other types of games can also be seen as an instance of FES, for example energy parity games \cite{CD12} are FES on the lattice $\mathbb{Z} \to \{\bot, \top\}$, ordered pointwise. A modern parity game solver is Oink \cite{vD18}.

Parameterised Boolean Equation Systems (PBES, also known as first-order, or predicate BES) arise as FES over the powerset lattice $(2^D, \subseteq)$, with $D$ some data type, typically representing the state space of a possibly infinite LTS. In \cite{Mat98, GM99}, PBES are proposed to encode the model-checking problem of first-order mu-calculus on infinite LTSs; they are studied in more detail in \cite{GW05b, GW05a}. An encoding of (branching) bisimulation of infinite LTSs in PBES is proposed in \cite{CPvdPW07}. Various procedures that operate on PBES have been studied, for example to simplify \cite{Nee22, OW10} or solve PBES \cite{NWG20, NWWV22, PWW11}. Algorithms for solving some timed fragments of PBES automatically are studied in \cite{ZC05}. PBES are implemented in the mCRL2 \cite{BGK19} and CADP \cite{GLMS13} model checking toolsets. MuArith \cite{KFG20} is similar to PBES, but the domain $D$ is restricted to integers.

Fixpoint Equation Systems over arbitrary complete lattices (FES) are defined in \cite{Mad97, TC02}. Some works refer to the same concept as Hierarchical Equation Systems (HES) \cite{Sei96, KNIU19}, Systems of Fixpoint Equations \cite{BKP20} or Nested Fixpoint Equations \cite{JMT22}. In \cite{ZC05} it is recognized that BES and PBES (and also Modal Equation Systems \cite{CS93}, an equational representation of the modal mu-calculus) are instances of FES. FESs are mainly useful to provide generic definitions for all these kinds of equation systems. We claim that the generic semantics of a FES is more elegant than the semantics of PBES, as given in e.g. \cite{GW05a}. In particular, equations in FES are defined in a semantic manner as functions on valuations, rather than on syntactic expressions (possibly with binders). Another advantage of FES is that one can derive a number of basic theorems for equation systems over all lattices in one stride, like in Chapter 3 of Mader’s thesis \cite{Mad97}.

Abstract dependency graphs \cite{EGLS19} are similar to FES, but variables range over a Noetherian partial order with a least element, instead of a complete lattice. When assuming every right-hand side is effectively computable, minimal fixpoints can be computed in an iterative fashion. Dependency graphs do not contain fixpoint alternations.

Contributions. Our main goal is to study basic operations on FES, related with substituting variables in the equations by their definition or final solution, or swapping the order of equations in the specification. Substitution operations form the basis of solving BES by so-called Gauss-elimination \cite{Mad97}. Also for PBES, Gauss elimination plays a crucial role in their solution. Reordering the variables in the specification is useful, because it may give rise to independent subspecifications that can be solved separately. Also, swapping the order of variables may bring down the number of alternations between $\mu$ and $\nu$, thus lowering the complexity of certain solution algorithms.

Our results consist of equalities and inequalities between FES, expressing under which conditions the basic operations preserve the solution of a FES. The main results are summarized in Table 1 (Section 7). In particular:

(1) Results on substitution for BES and PBES are generalized to FES.
(2) Results on swapping variables are generalized and sorted out, by weakening existing conditions, and by providing alternative conditions.
(3) We provide rigorous proofs of our results. All proofs in this paper have been proof-checked mechanically by the Coq theorem prover \cite{Ber08, S+23} (version 8.17) as well as the PVS theorem prover \cite{OS08} (version 7.1). Our proofs are available online \cite{NvdP24}.
Overview. We first provide the basic theory of complete lattices in Section 2 and reprove all needed facts on fixpoints, in order to present a self-contained account. The formal definition and semantics of Fixpoint Equation Systems is provided in Section 3. The proofs (Section 4, 5 and 6) are quite elementary. They are mainly based on induction (to deal with the recursive definition of FES semantics, Section 3.1) and on identities and inequalities on fixpoints in complete lattices. In Section 7, we provide examples of applications of our theory and discuss its relation with the literature. Finally, we highlight several aspects of our Coq and PVS formalisations in Section 8.

2. Fixpoint Laws in Complete Lattices

A partial order on a universe $U$ is a binary relation $\leq \subseteq U \times U$, which is reflexive ($\forall x. x \leq x$), anti-symmetric ($\forall x, y. x \leq y \land y \leq x \Rightarrow x = y$) and transitive ($\forall x, y, z. x \leq y \land y \leq z \Rightarrow x \leq z$), where in all cases $x, y, z \in U$.

Given partial orders $(U, \leq)$ and $(V, \leq)$, we define partial orders $(U \times V, \leq)$ and $(U \rightarrow V, \leq)$ pointwise: $(u_1, v_1) \leq (u_2, v_2) \iff u_1 \leq u_2 \land v_1 \leq v_2$, and $f \leq g$ iff $\forall x \in U. f(x) \leq g(x)$. Function $f : U \rightarrow V$ is called monotonic, iff $\forall x, y. x \leq y \Rightarrow f(x) \leq f(y)$.

Given a set $X \subseteq U$, we define its set of lower bounds in $U$ as $\text{lub}(X) := \{ y \in U \mid \forall x \in X. y \leq x \}$. If $y \in \text{lub}(X)$ and $z \leq y$ for all $z \in \text{lub}(X)$, then $y$ is called the greatest lower bound of $X$. A complete lattice is a triple $(U, \leq, \text{glb})$, where $\leq$ is a partial order, and $\text{glb}(X)$ returns the greatest lower bound of $X$ in $U$, for all (finite or infinite) $X \subseteq U$.

Given a complete lattice $(U, \leq, \text{glb})$, define the partial order $(U, \geq)$, by $x \geq y$ iff $y \leq x$. We define the set of upper bounds of $X \subseteq U$ by $\text{ub}(X) := \{ y \in U \mid \forall x \in X. y \geq x \}$. Define $\text{lub}(X) := \text{glb}(\text{ub}(X))$. Clearly, for all $y \in \text{ub}(X)$, $\text{lub}(X) \leq y$. But also $\text{lub}(X) \in \text{ub}(X)$, for if $x \in X$, then $x \in \text{ub}(\text{ub}(X))$, hence $x \leq \text{glb}(\text{ub}(X))$. So $\text{lub}(X)$ yields the least upper bound of $X$, and $(U, \geq, \text{lub})$ is a complete lattice as well.

Given a complete lattice $(U, \leq, \text{glb})$, we define the least fixpoint ($\mu$) and greatest fixpoint ($\nu$) of any function $f : U \rightarrow U$ (not only for monotonic) as follows:

\[
\begin{align*}
\mu(f) & := \text{glb}\{x \mid f(x) \leq x\} \\
\nu(f) & := \text{lub}\{x \mid x \leq f(x)\}
\end{align*}
\]

For $\sigma \in \{\mu, \nu\}$, we abbreviate $\sigma(\lambda x. f(x))$ by $\sigma x. f(x)$. Note that by definition, $\nu$ in $(U, \leq, \text{glb})$ equals $\mu$ in $(U, \geq, \text{lub})$, so theorems on $(\mu, \leq)$ hold for $(\nu, \geq)$ as well “by duality”. Also note that $F : U \rightarrow U$ is monotonic in $(U, \leq)$ if and only if it is monotonic in $(U, \geq)$. A direct consequence of the definition of $\mu$ is the following principle (and its dual):

\[
\begin{align*}
f(x) \leq x & \Rightarrow \mu(f) \leq x \quad \text{(\mu-fixpoint induction)} \\
x \leq f(x) & \Rightarrow x \leq \nu(f) \quad \text{(\nu-fixpoint induction)}
\end{align*}
\]

We now have the following identities on fixpoint expressions:

**Lemma 2.1.** Let $(U, \leq, \text{glb})$ be a complete lattice. Let $\sigma \in \{\mu, \nu\}$, $A \in U$, and let $F, G \in U \rightarrow U$ and $H, K \in U \times U \rightarrow U$ be monotonic functions. Then:

1. $F(\sigma(F)) = \sigma(F)$ \hspace{1cm} (computation rule)
2. $\sigma x. A = A$ \hspace{1cm} (constant rule)
3. $\sigma x. F(G(x)) = F(\sigma x. G(F(x)))$ \hspace{1cm} (rolling rule)
4. $\sigma x. F(F(x)) = \sigma x. F(x)$ \hspace{1cm} (square rule)
5. $\sigma$ is monotonic \hspace{1cm} (fixpoint monotonicity)
6. $\sigma x. H(x, x) = \sigma x. \sigma y. H(x, y)$ \hspace{1cm} (diagonal rule)
Proof. We first prove the theorem for \( \sigma = \mu \). By the observations above, the theorem then follows for \( \sigma = \nu \) as well (“by duality”).

(1) (a) Let \( y \) with \( F(y) \leq y \) be given. Then by fixpoint induction,
\[
\mu(F) \leq y.
\]
By monotonicity, \( F(\mu(F)) \leq F(y) \leq y \). Since \( y \) is arbitrary, \( F(\mu(F)) \) is a lower bound of \( \{x \mid F(x) \leq x\} \). Hence \( F(\mu(F)) \leq \text{glb}(\{x \mid F(x) \leq x\}) = \mu(F) \).

(b) \( F(\mu(F)) \leq \mu(F) \) by (a), so by monotonicity,
\[
F(F(\mu(F))) \leq F(\mu(F)).
\]
By fixpoint induction, \( \mu(F) \leq F(\mu(F)) \).

Then by anti-symmetry, \( F(\mu(F)) = \mu(F) \).

(2) Follows directly from (1) by taking \( F := \lambda x. A \) (which is monotonic).

(3) Obviously, \( \lambda x. F(G(x)) \) and \( \lambda x. G(F(x)) \) are monotonic.

(a) By (1), \( F(G(\mu x. G(F(x)))) = F(\mu x. G(F(x))) \). Hence by fixpoint induction, \( \mu x. F(G(x)) \leq F(\mu x. G(F(x))) \).

(b) \[
G(F(G(\mu x. G(F(x))))) \overset{(1)}{=} G(\mu x. F(G(x)))
\]
\[
\Rightarrow \text{ (by fixpoint induction)}
\]
\[
\mu x. F(G(x)) \leq G(\mu x. F(G(x)))
\]
\[
\Rightarrow \text{ (by monotonicity)}
\]
\[
F(\mu x. G(F(x))) \leq F(G(\mu x. F(G(x)))) \overset{(1)}{=} \mu x. F(G(x))
\]
By anti-symmetry, we obtain \( \mu x. F(G(x)) = F(\mu x. G(F(x))) \).

(4) (a) Using (1) twice, \( F(F(\mu x. F(x))) = F(\mu x. F(x)) = \mu x. F(x) \). So by fixpoint induction, \( \mu x. F(F(x)) \leq \mu x. F(x) \).

(b) By (3), we get \( F(\mu x. F(F(x))) = \mu x. F(F(x)) \). Hence by fixpoint induction, \( \mu x. F(x) \leq \mu x. F(F(x)) \).

Then by anti-symmetry, \( \mu x. F(F(x)) = \mu x. F(x) \).

(5) Assume \( f \leq g \). Let \( y \) with \( g(y) \leq y \) be given. Then \( f(y) \leq g(y) \leq y \), so \( \mu(f) \leq y \) by fixpoint induction. Since \( y \) is arbitrary, \( \mu(f) \) is a lower bound for \( \{x \mid g(x) \leq x\} \). By definition \( \mu(g) \) is its greatest lower bound, so \( \mu(f) \leq \mu(g) \).

(6) (a) \[
H(\mu x. H(x,x), \mu x. H(x,x)) \overset{(1)}{=} \mu x. H(x,x)
\]
\[
\Rightarrow \text{ (by fixpoint induction, applied with } F := \lambda x. H(x,x))
\]
\[
\mu y. H(\mu x. H(x,x), y) \leq \mu x. H(x,x)
\]
\[
\Rightarrow \text{ (by fixpoint induction)}
\]
\[
\mu x. \mu y. H(x,y) \leq \mu x. H(x,x)
\]

(b) Let us abbreviate \( A := \mu x. \mu y. H(x,y) \). Using (5) one can show that \( \lambda x. \mu y. H(x,y) \) is monotonic. Then:
\[
A \overset{(1)}{=} \mu y. H(A,y) \overset{(1)}{=} H(A, \mu y. H(A,y))
\]
\[
\Rightarrow \text{ (by congruence and both equations above)}
\]
\[
H(A,A) = H(A, \mu y. H(A,y)) = A
\]
\[ \Rightarrow \text{(by fixpoint induction)} \]
\[ \mu x. H(x, x) \leq A = \mu x. \mu y. H(x, y) \]

By anti-symmetry, we indeed get: \( \mu x. H(x, x) = \mu x. \mu y. H(x, y) \).

(7) Using (4) on \( \lambda y. H(x, y) \) yields \( \mu x. \mu y. H(x, y) = \mu x. \mu y. H(x, H(x, x)) \). Applying (6) to both sides yields \( \mu x. H(x, x) = \mu x. H(x, H(x, x)) \).

(8) We use (6) twice on the function \( \lambda (y, x) . H(x, y) \):

\[
\begin{align*}
\mu x. H(x, x) & \overset{(6)}{=} \mu y. \mu x. H(x, y) \\
& \overset{(1)}{=} \mu x. H(x, \mu y. \mu x. H(x, y)) \\
& \overset{(6)}{=} \mu x. H(x, \mu x. H(x, x))
\end{align*}
\]

(9) Define \( F(y) := \mu x. H(x, y) \) and \( G(y) := \mu x. K(x, y) \). Then:

\[
\begin{align*}
\mu y. F(G(y)) & \overset{(3)}{=} F(\mu y. G(F(y))) \\
\Rightarrow & \text{(by definition of } F, G) \\
\mu y. \mu x. H(x, G(y)) & = F(\mu y. \mu x. K(x, F(y))) \\
& \Rightarrow \text{(by } 6, \text{ applied to left- and right-hand side)} \\
\mu x. H(x, G(x)) & = F(\mu y. K(y, F(y))) \\
& \Rightarrow \text{(by definition of } F, G) \\
\mu x. (H(x, \mu y. K(y, x))) & = \mu x. H(x, \mu y. K(y, \mu z. H(z, y)))
\end{align*}
\]

A careful analysis shows that all these identities can be derived in an equational style from the identities 1, 3, 4 and 6. A natural question is whether all true equalities (with \( \mu \) as second order operation, and variables ranging over monotonic functions) can be derived from these four identities in an equational manner (thus excluding the fixpoint induction rule). We don’t know the answer, but we expect that at least the equations \( \mu x. F(x) = \mu x. F^p(x) \) are needed for all primes \( p \). Results from universal algebra don’t apply directly, due to the second order nature of the fixpoint operator.

By mixing least and greatest fixpoints, we also obtain a number of inequalities. In particular, 4 is new, as far as we know. Note the similarity of (4) with Bekić Rule, Lemma 2.1. We will call (4) Bekić Inequality.

**Lemma 2.2.** Let \( (U, \leq, \text{glb}) \) be a complete lattice. Let \( \sigma \in \{\mu, \nu\}, A \in U, \) and let \( F, G \in U \longrightarrow U \) and \( H, K \in U \times U \longrightarrow U \) be monotonic functions. Then:

1. \( \mu (F) \leq \nu (F) \)
2. \( \mu x. x \leq A \)
   a. \( A \leq \nu x. x \)
3. \( \mu x. \nu y. H(x, y) \leq \nu y. \mu x. H(x, y) \)
4. \( \mu x. H(x, \nu y. K(y, x)) \leq \mu x. H(x, \nu y. K(y, \mu x. H(x, y))) \)
   a. \( \nu x. H(x, \mu y. K(y, x)) \geq \nu x. H(x, \mu y. K(y, \nu x. H(x, y))) \)

**Proof.**

1. \( F(\nu(F)) \overset{(2.1.1)}{=} \nu(F), \text{ so by fixpoint induction, } \mu (F) \leq \nu (F) \).
2. (a) \( A \leq A \), hence by fixpoint induction, \( \mu x. x \leq A \). Then (b) follows by duality.
(3) Define $F(x) := \nu y. H(x, y)$ and $G(y) := \mu x. H(x, y)$. Note that both $F$ and $G$ are monotonic, using Lemma 2.1.5. Then:
\[
\begin{align*}
\mu(F) &\overset{(2.1.1)}{=} F(\mu(F)) \overset{(2.1.1)}{=} H(\mu(F), F(\mu(F))) \overset{(2.1.1)}{=} H(\mu(F), \mu(F)) \\
\Rightarrow \quad \text{(by fixpoint induction)} \\
G(\mu(F)) &= \mu x. H(x, \mu(F)) \leq \mu(F) \\
\Rightarrow \quad \text{(monotonicity $F$)} \\
F(G(\mu(F))) &\leq F(\mu(F)) \overset{(2.1.1)}{=} \mu(F) \\
\Rightarrow \quad \text{(monotonicity $H$)} \\
F(G(\mu(F))) &\overset{(2.1.1)}{=} H(G(\mu(F)), F(G(\mu(F)))) \leq H(G(\mu(F)), \mu(F)) \overset{(2.1.1)}{=} G(\mu(F)) \\
\Rightarrow \quad \text{(by fixpoint induction)} \\
\mu(F) &\leq G(\mu(F)) \\
\Rightarrow \quad \text{(by fixpoint induction for $\nu$)} \\
\mu(F) &\leq \nu(G)
\end{align*}
\]

(4) (a) Define $F(y) := \mu x. H(x, y)$ and $G(x) := \nu y. K(y, x)$. Note that both $F$ and $G$ are monotonic, using Lemma 2.1.5. Then:
\[
\begin{align*}
\mu x. H(x, \nu y. K(y, x)) &\overset{(2.1.6)}{=} \mu x. \mu z. H(z, \nu y. K(y, x)) \\
&= \mu x. F(G(x)) \\
&\overset{(2.1.3)}{=} F(\mu x. G(F(x))) \\
&\leq \quad \text{(using 1, and monotonicity of $F$)} \\
F(\nu x. G(F(x))) &= F(\nu x. \nu y. K(y, F(x))) \\
&\overset{(2.1.6)}{=} F(\nu y. K(y, F(y))) \\
&= \mu x. H(x, \nu y. K(y, \mu x. H(x, y)))
\end{align*}
\]

Then (b) follows by “duality” (reversing $\mu/\nu$ and $\leq/\geq$). More precisely, (b) is (a) in the reversed complete lattice $(U, \geq, \text{lub})$. \hfill \Box

Note that (1) and (3) are their own dual.

3. Fixpoint Equation Systems

In this section we first formally define Fixpoint Equation Systems (FES). We show by examples how they generalize Boolean and Predicate Equation Systems. Subsection 3.2 introduces the semantics of a FES by defining its solutions. Finally, Subsection 3.3 defines the variable dependency graph in a FES.
3.1. Definition of Fixpoint Equation Systems. Fix a complete lattice \((U, \leq, \text{glb})\), and a set of variables \(X\). Throughout the paper, we assume that equality on variables is decidable.

We define the set of valuations \(\text{Val} := X \rightarrow U\). For \(X \in X\), \(\eta \in \text{Val}\), \(P \in U\), we denote by \(\eta[X := P]\) the valuation that returns \(P\) on \(X\) and \(\eta(Y)\) on \(Y \neq X\). As any function, valuations can be ordered pointwise, i.e. \(\eta_1 \leq \eta_2\) iff \(\forall X \in X. \eta_1(X) \leq \eta_2(X)\). Note thatvaluation update is monotonic, that is, if \(P \leq Q\), then \(\eta[X := P] \leq \eta[X := Q]\). To indicate that two valuations agree on a set of variables \(V \subseteq X\), we write \(\eta_1 \leq \eta_2\), formally defined as \(\forall X \in V.\eta_1(X) = \eta_2(X)\). The complement of \(V\) in \(X\) is denoted \(\overline{V}\).

A set of mutually recursive equations is a member of \(\mathcal{Eqs} := \text{Val} \rightarrow \text{Val}\). The set \(\mathcal{Eqs}\) is also ordered pointwise. \(\mathcal{E}\) is monotonic iff it is a monotonic function on \(\text{Val}\). Note that this semantic view on equations escapes the need to introduce (and be limited) to a particular syntax.

Example 3.1. Take \(X = \{X, Y, Z\}\) and \(U = \mathbb{B}\), the Boolean lattice \(\perp < \top\). We write \((a, b, c) \in \mathbb{B}^3\) as a shorthand for the valuation \(\{X=a, Y=b, Z=c\}\). The system of equations \(\{X = Y \land Z, Y = X \lor Z, Z = \neg X\}\) is represented in our theory as the function

\[
\mathcal{B} := \lambda(X, Y, Z) \in \mathbb{B}^3. (Y \land Z, X \lor Z, \neg X).
\]

It is not monotonic, because as valuations, \((\perp, \perp, \perp) \leq (\top, \top, \top)\), but

\[
\mathcal{B}(\perp, \perp, \perp) = (\perp, \perp, \top) \not\leq (\top, \top, \top) = \mathcal{B}(\top, \top, \top).
\]

Note that \(\mathcal{Eqs}\) is isomorphic with \(X \rightarrow \text{Val} \rightarrow \text{Val}\). This motivates the following slight abuse of notation: Given \(\mathcal{E} \in \mathcal{Eqs}\), we will often write \(\mathcal{E}_X(\eta)\) for \(\mathcal{E}(\eta)(X)\). This expression denotes the definition of \(X\) in \(\mathcal{E}\), possibly depending on other variables as represented by the valuation \(\eta\). Similar to valuations, agreement on variables from \(V \subseteq X\) is denoted \(\mathcal{E}_1 \preceq \mathcal{E}_2\), defined as \(\forall \eta \in \text{Val}, X \in V.\mathcal{E}_1(\eta)(X) = \mathcal{E}_2(\eta)(X)\).

The set of specifications consists of finite lists of signed variables: \(\mathcal{Spec} := (\{\mu, \nu\} \times X)^*\). Note that a specification selects a subset of variables to be considered, assigns a fixpoint sign to these variables, and assigns an order to these variables. We use \(\sigma X\) as a notation for \((\sigma, X)\), write \(\epsilon\) for the empty list, and use \(;\) for list concatenation. We will identify a singleton list with its element. For instance, \([\mu X, \nu Y];\mu Z\) denotes the specification \([\{\mu, X\}, \{\nu, Y\}, \{\mu, Z\}]\). We define \(\text{dom}(\mathcal{S}) \subseteq X\) as the set of variables that occur in some pair in \(\mathcal{S}\). Decidability of \(X \in \text{dom}(\mathcal{S})\) follows from finiteness of \(\mathcal{S}\) and decidability of equality on variables. We define \(\text{disjoint}(\mathcal{S}_1, \mathcal{S}_2)\) iff \(\text{dom}(\mathcal{S}_1) \cap \text{dom}(\mathcal{S}_2) = \emptyset\).

We often require that valuations or equation systems agree on the variables in a specification. Accordingly, we overload \(\preceq\) so that \(\eta_1 \preceq \eta_2\) (resp. \(\mathcal{E}_1 \preceq \mathcal{E}_2\)) is defined as \(\eta_1 \preceq \text{dom}(\mathcal{S}) \eta_2\) (resp. \(\mathcal{E}_1 \preceq \mathcal{E}_2\)). This also applies when a complement is involved: \(\eta_1 \equiv \eta_2\) is \(\eta_1 \equiv \text{dom}(\mathcal{S}) \eta_2\).

Finally, a fixpoint equation system (FES) \(\mathcal{F}\) on \((U, X)\) is simply a pair in \(\mathcal{Fes} := \mathcal{Eqs} \times \mathcal{Spec}\). Before we present the semantics of FES, we first consider several instances of FES.

Example 3.2. The Boolean Equation System [Mad97] traditionally written as

\[
\begin{align*}
\mu X &= Y \land Z \\
\nu Y &= X \lor Z \\
\nu Z &= \neg X
\end{align*}
\]

is represented in our theory as the pair \(\mathcal{B}, [\mu X, \nu Y, \nu Z]\), where \(\mathcal{B}\) is from Example 3.1. Note that this notation for BES integrates the set of equations and the specification into one, and these cannot be considered separately.
Example 3.3. A PBES (parameterized BES [GW05a], or predicate equation system [ZC05]) is a FES over the complete lattice $U := (\mathcal{P}(D), \subseteq)$ for some data set $D$, or equivalently $(D \to \mathbb{B}, \leq)$. PBES thus generalise BES: each variable is now a predicate over domain $D$, allowing one to create complex expressions over data. For our example, let $\mathcal{X} = \{X, Y\}$ and $D = \mathbb{N} \times \mathbb{B}$. Again using the shorthand $(X, Y) \in (D \to \mathbb{B})^2$ for valuations, $(B', [\mu X, \nu Y])$ is a PBES, where

$$B' := (\lambda(X, Y) \in (D \to \mathbb{B})^2.$$

$$= (\lambda m \in \mathbb{N}, b \in \mathbb{B}. (b \to m > 0 \land Y(m, \bot)) \land (\neg b \to m < 5 \land Y(m, \bot)),$$

$$\lambda m \in \mathbb{N}, b \in \mathbb{B}. X(m - 1, m > 4) \lor Y(m + 1, \bot))$$

The function on the last line, which defines $Y$, does not contain an occurrence of the argument $b$. However, in our theory we are required to include it so that both variables in $\mathcal{X} := \{X, Y\}$ are predicates over the same $D := \mathbb{N} \times \mathbb{B}$. In the notation of [GW05a], the same PBES is simply written as a pair of predicate definitions with accompanying fixpoint signs. The argument $b$ of $Y$ may be left out:

$$\mu X(m; \mathbb{N}, b; \mathbb{B}) = (b \to m > 0 \land Y(m)) \land (\neg b \to m < 5 \land Y(m))$$

$$\nu Y(m; \mathbb{N}) = X(m - 1, m > 4) \lor Y(m + 1)$$

Similar to BES, the PBES formalism as defined in [GW05a] does not consider the equations and the specification separately.

Remark 3.4. Our choice of separating the set of equations and the specification makes it easier to perform induction proofs over the specification (because one retains knowledge of all equations in the proof scope). However, we have not required that all variables in $S$ are unique. This is not needed in our formalization, because in Lemma 3.7.3 we will show that if $X \in \text{dom}(S)$, then any set of equations $E$ has the same semantics when combined with $S$ or with $\sigma X; S$ for any $\sigma \in \{\mu, \nu\}$. Do note that there is a hidden assumption: even if $X$ occurs multiple times in $S$, possibly with different signs, there can only be one defining equation for it, because $E$ is a function. So when transferring the results to traditional notation, one should add the (quite natural) requirement that all equations have unique variable names.

Example 3.5. Modal equation systems (MES) [CS93] is a very similar FES instance to PBES since it also uses the powerset lattice $(\mathcal{P}(D), \subseteq)$. However, a MES is interpreted on a labelled transition system (LTS), so that $D$ is equal to the set of states in the LTS. MES includes, for every action $a$ in the LTS, the modal operators $[a] \varphi$ (“$\varphi$ must hold after every possible transition labelled with $a$”) and $\langle a \rangle \varphi$ (“there exists an $a$-transition after which $\varphi$ holds”). MES is an equational representation of the modal mu-calculus. Adopting the notation from the previous examples, an example of a MES is:

$$\nu X = Y$$

$$\mu Y = [a]X \land [b]Y$$

This MES expresses that on every path in the LTS, action $a$ occurs infinitely often (and $b$ may happen only finitely often in between).
3.2. Semantics of FES and Basic Results. Next, the semantics of a FES, $[\mathcal{E}, \mathcal{S}] : \text{Val} \rightarrow \text{Val}$, is defined recursively on $\mathcal{S}$:

$$
\begin{align*}
[\mathcal{E}, \varepsilon](\eta) &:= \eta \\
[\mathcal{E}, \sigma X : \mathcal{S}](\eta) &:= [\mathcal{E}, \mathcal{S}](\eta[X := \sigma(F)]),
\end{align*}
$$

where $F : U \rightarrow U$ is defined as $F(P) := \mathcal{E}_X([\mathcal{E}, \mathcal{S}](\eta[X := P]))$

We now state the first results on the semantics of FES. The lemma below states monotonicity properties for the semantics. They ensure that fixpoints are well-behaved. Below, recall that we use pointwise ordering, e.g., $\mathcal{E}_1 \leq \mathcal{E}_2$ iff $\mathcal{E}_1(\eta)(X) \leq \mathcal{E}_2(\eta)(X)$ for all $\eta$ and $X$.

**Lemma 3.6.** Let $\mathcal{E}, \mathcal{E}_1, \mathcal{E}_2 \in \mathcal{Egs}$ and $\mathcal{S} \in \text{Spec}$, then

1. If $\mathcal{E}$ is monotonic, then $[\mathcal{E}, \mathcal{S}]$ is monotonic.
2. If $\mathcal{E}_1$ is monotonic and $\mathcal{E}_1 \leq \mathcal{E}_2$, then $[\mathcal{E}_1, \mathcal{S}] \leq [\mathcal{E}_2, \mathcal{S}]$.

**Proof.**

(1) We prove $\forall \eta_1, \eta_2. \eta_1 \leq \eta_2 \Rightarrow [\mathcal{E}, \mathcal{S}](\eta_1) \leq [\mathcal{E}, \mathcal{S}](\eta_2)$ by induction on $\mathcal{S}$. The base case: assume $\eta_1 \leq \eta_2$, then $[\mathcal{E}, \varepsilon](\eta_1) = \eta_1 \leq \eta_2 = [\mathcal{E}, \varepsilon](\eta_2)$. Induction step: Let $\eta_1 \leq \eta_2$ be given, then for any $P \in U$, we have $\eta_1[X := P] \leq \eta_2[X := P]$. So

(induction hypothesis)

$$
[\mathcal{E}, \mathcal{S}](\eta_1[X := P]) \leq [\mathcal{E}, \mathcal{S}](\eta_2[X := P])
$$

$\Rightarrow$ (induction hypothesis)

$$
[\mathcal{E}, \mathcal{S}](\eta_1[X := P]) \leq [\mathcal{E}, \mathcal{S}](\eta_2[X := P])
$$

$\Rightarrow$ (definition)

$$
[\mathcal{E}, \mathcal{S}](\eta_1[X := \sigma(F_1)]) \leq [\mathcal{E}, \mathcal{S}](\eta_2[X := \sigma(F_2)])
$$

$\Rightarrow$ (definition)

$$
[\mathcal{E}, \mathcal{S}](\eta_1) \leq [\mathcal{E}, \mathcal{S}](\eta_2)
$$

(2) Assume $\mathcal{E}_1$ is monotonic, and $\mathcal{E}_1 \leq \mathcal{E}_2$ (pointwise). We prove by induction on $\mathcal{S}$ that $\forall \eta. [\mathcal{E}_1, \mathcal{S}](\eta) \leq [\mathcal{E}_2, \mathcal{S}](\eta)$. The base case is simple: for all $\eta$, we have $[\mathcal{E}_1, \varepsilon](\eta) = \eta = [\mathcal{E}_2, \varepsilon](\eta)$. For the induction step, let $\eta$ be given, then for any $P \in U$:

(induction hypothesis)

$$
[\mathcal{E}_1, \mathcal{S}](\eta[X := P]) \leq [\mathcal{E}_2, \mathcal{S}](\eta[X := P])
$$

$\Rightarrow$ (monotonicity of $\mathcal{E}_1$ and $\mathcal{E}_1 \leq \mathcal{E}_2$, pointwise)

$$
[\mathcal{E}_1, \mathcal{S}](\eta[X := P]) \leq [\mathcal{E}_2, \mathcal{S}](\eta[X := P])
$$

$\Rightarrow$ (definition)

$$
[\mathcal{E}_1, \mathcal{S}](\eta[X := \sigma(F_1)]) \leq [\mathcal{E}_2, \mathcal{S}](\eta[X := \sigma(F_2)])
$$

$\Rightarrow$ (definition)

$$
[\mathcal{E}_1, \mathcal{S}](\eta) \leq [\mathcal{E}_2, \mathcal{S}](\eta)
$$
\[
\eta[X := \sigma(F_1)] \leq \eta[X := \sigma(F_2)]
\]
\[
\Rightarrow \quad [\mathcal{E}_1, \mathcal{S}](\eta[X := \sigma(F_1)]) \leq [\mathcal{E}_1, \mathcal{S}](\eta[X := \sigma(F_2)])
\]
\[
\leq \quad \text{(monotonicity, part 1 of this lemma)}
\]
\[
[\mathcal{E}_1, \mathcal{S}](\eta[X := \sigma(F_2)]) \leq \quad \text{(induction hypothesis)}
\]
\[
[\mathcal{E}_2, \mathcal{S}](\eta[X := \sigma(F_2)])
\]
\[
\Rightarrow \quad \text{(definition)}
\]
\[
[\mathcal{E}_1, \sigma X; \mathcal{S}](\eta) \leq [\mathcal{E}_2, \sigma X; \mathcal{S}](\eta)
\]

The next lemma states three sanity properties of the semantics: (1) The semantics only modifies the valuation on elements in the domain; (2) the semantics only depends on equations mentioned in the domain; (3) the input valuation is only used for variables outside the domain.

**Lemma 3.7.** Let \( \mathcal{E}, \mathcal{E}_1, \mathcal{E}_2 \in \mathcal{E}qs, \mathcal{S} \in \text{Spec}, \eta \in \text{Val} \) and \( X \in \mathcal{X} \).

1. If \( X \notin \text{dom}(\mathcal{S}) \) then \( [\mathcal{E}, \mathcal{S}](\eta)(X) = \eta(X) \).
2. If \( \mathcal{E}_1 \trianglelefteq \mathcal{E}_2 \), then \([\mathcal{E}_1, \mathcal{S}] = [\mathcal{E}_2, \mathcal{S}]\).
3. If \( \eta_1 \equiv \eta_2 \), then \([\mathcal{E}, \mathcal{S}](\eta_1) = [\mathcal{E}, \mathcal{S}](\eta_2)\).

**Proof.**

1. Induction on \( \mathcal{S} \). The base case holds by definition. For the induction step, assume \( X \notin \text{dom}(\sigma Y; \mathcal{S}) \). Then

\[
[\mathcal{E}, \sigma Y; \mathcal{S}](\eta)(X)\]
\[
= \quad \text{(define } F(P) := \mathcal{E}_Y([\mathcal{E}, \mathcal{S}](\eta[Y := P]))\text{)}
\]
\[
[\mathcal{E}, \mathcal{S}](\eta[Y := \sigma(F)])(X)\]
\[
= \quad \text{(induction hypothesis, note: } X \notin \text{dom}(\mathcal{S})\text{)}
\]
\[
\eta[Y := \sigma(F)](X)\]
\[
= \quad \text{(} X \notin \text{dom}(\sigma Y; \mathcal{S}), \text{ so } X \neq Y\text{)}
\]
\[
\eta(X)
\]

2. Induction on \( \mathcal{S} \). The base case holds by definition. For the induction step, let \( \eta \) be given, and assume \( \mathcal{E}_1 \sigma X; \mathcal{S} \mathcal{E}_2 \). Note that this implies \( \mathcal{E}_1 \trianglelefteq \mathcal{E}_2 \), so we can use the induction hypothesis. For any \( P \in U \) we have:

\[
\text{(induction hypothesis)}
\]
\[
[\mathcal{E}_1, \mathcal{S}](\eta[X := P]) = [\mathcal{E}_2, \mathcal{S}](\eta[X := P])
\]
\[
\Rightarrow \quad \text{(} X \in \text{dom}(\sigma X; \mathcal{S}), \text{ so } \mathcal{E}_{1,X} = \mathcal{E}_{2,X} \text{ by assumption)}
\]
\[
\mathcal{E}_{1,X}([\mathcal{E}_1, \mathcal{S}](\eta[X := P])) = \mathcal{E}_{2,X}([\mathcal{E}_2, \mathcal{S}](\eta[X := P]))
\]
\[
\Rightarrow \quad \text{(define } F_i(P) := \mathcal{E}_{i,X}([\mathcal{E}_i, \mathcal{S}](\eta[X := P])) \text{ for } i = 1, 2\text{)}
\]
\[
\eta[X := \sigma(F_1)] = \eta[X := \sigma(F_2)]
\]
\[
\Rightarrow \quad \text{(induction hypothesis)}
\]
\[
[\mathcal{E}_1, \mathcal{S}](\eta[X := \sigma(F_1)]) = [\mathcal{E}_2, \mathcal{S}](\eta[X := \sigma(F_2)])
\]
\[
\Leftrightarrow \quad \text{(definition)}
\]
(3) Induction on $S$. The base case is trivial, because both the assumption and the conclusion reduce to $\eta_1 = \eta_2$. The induction step is proved as follows (for arbitrary $P \in U$):

\[ \eta_1 \overset{\sigma X}{=} \eta_2 \]  
\Rightarrow (extensionality)  
\[ \eta_1[X := P] \overset{\overline{S}}{=} \eta_2[X := P] \]  
\Rightarrow (induction hypothesis)  
\[ \llbracket E, S \rrbracket[\eta_1[X := P]] = \llbracket E, S \rrbracket[\eta_2[X := P]] \]  
\Rightarrow (define \( F_i(P) := E_X(\llbracket E, S \rrbracket[\eta_i[X := P]]) \), for \( i = 1, 2 \))  
\[ \sigma(F_1) = \sigma(F_2) \]  
\Rightarrow (extensionality)  
\[ \eta_1[X := \sigma(F_1)] \overset{\overline{S}}{=} \eta_2[X := \sigma(F_2)] \]  
\Rightarrow (induction hypothesis)  
\[ \llbracket E, S \rrbracket[\eta_1[X := \sigma(F_1)]] = \llbracket E, S \rrbracket[\eta_2[X := \sigma(F_2)]] \]  
\Rightarrow (definition)  
\[ \llbracket E, \sigma X; S \rrbracket[\eta_1] = \llbracket E, \sigma X; S \rrbracket[\eta_2] \]  
\[ \square \]

Next, we can prove that the semantics as defined above indeed solves the equations for those variables occurring in the specification:

**Lemma 3.8.** Let $E \in \text{Eqs}$ be monotonic, $S \in \text{Spec}$, $\eta \in \text{Val}$ and $X \in \mathcal{X}$.
If $X \in \text{dom}(S)$, then $E_X(\llbracket E, S \rrbracket[\eta]) = \llbracket E, S \rrbracket[\eta](X)$.

**Proof.** Let $E$ be monotonic. By induction on $S$, we will prove that for all $X \in \text{dom}(S)$ and for all $\eta$, it holds that $E_X(\llbracket E, S \rrbracket[\eta]) = \llbracket E, S \rrbracket[\eta](X)$. The base case trivially holds, because $X \notin \text{dom}(\epsilon)$. For the induction step, assume $X \in \text{dom}(\sigma Y; S)$. We distinguish cases.

If $X \in \text{dom}(S)$:

\[ \llbracket E, \sigma Y; S \rrbracket[\eta](X) \]
\[ = (\text{define } F(P) := E_Y(\llbracket E, S \rrbracket[\eta[Y := P]])) \]
\[ \llbracket E, S \rrbracket[\eta[Y := \sigma(F)]](X) \]
\[ = (\text{induction hypothesis}; X \in \text{dom}(S)) \]
\[ E_X(\llbracket E, S \rrbracket[\eta[Y := \sigma(F)]])) \]
\[ = (\text{definition}) \]
\[ E_X(\llbracket E, \sigma Y; S \rrbracket[\eta]) \]

Otherwise, if $X \notin \text{dom}(S)$ then $X = Y$. We compute:

\[ \llbracket E, \sigma X; S \rrbracket[\eta](X) \]
\[ = (\text{define } F(P) := E_X(\llbracket E, S \rrbracket[\eta[X := P]])) \]
\[ \llbracket E, S \rrbracket[\eta[X := \sigma(F)]](X) \]
\[
\begin{align*}
&= (\text{Lemma 3.7.1; } X \notin \text{dom}(S)) \\
&\quad \sigma(F) \\
&= (\text{computation rule, Lemma 2.1.1; } F \text{ is monotonic because } \mathcal{E}_X \\
&\quad \text{is monotonic by assumption, and } [\mathcal{E}, S] \text{ is by Lemma 3.6.1}) \\
&\quad F(\sigma(F)) \\
&= \mathcal{E}_X([\mathcal{E}, S](\eta[X := \sigma(F)])) \\
&= (\text{definition}) \\
&\quad \mathcal{E}_X([\mathcal{E}, \sigma X; S](\eta))
\end{align*}
\]

We have the following left-congruence result:

**Lemma 3.9.** For \( \mathcal{E}_1, \mathcal{E}_2 \in \mathcal{E}_{qs} \), \( S, S_1, S_2 \in \text{Spec} \), if \( \mathcal{E}_1 \succeq \mathcal{E}_2 \) and \( [\mathcal{E}_1, S_1] = [\mathcal{E}_2, S_2] \), then \( [\mathcal{E}_1, S; S_1] = [\mathcal{E}_2, S; S_2] \).

**Proof.** Induction on \( S \). The base case is trivial. For the induction step, assume \( [\mathcal{E}_1, S_1] = [\mathcal{E}_2, S_2] \) and \( \mathcal{E}_1 \sigma X S \mathcal{E}_2 \). Then also \( \mathcal{E}_1 \succeq \mathcal{E}_2 \). So, for any \( P \in U \):

1. (induction hypothesis)
   \( [\mathcal{E}_1, S; S_1](\eta[X := P]) = [\mathcal{E}_2, S; S_2](\eta[X := P]) \)
2. \( \Rightarrow (\text{define } F_1(P) := \mathcal{E}_{1,X}(\mathcal{E}_{1,S;S_1}(\eta[X := P])); \text{ note } \mathcal{E}_{1,X} = \mathcal{E}_{2,X}) \)
   \( \eta[X := \sigma(F_1)] = \eta[X := \sigma(F_2)] \)
3. \( \Rightarrow (\text{induction hypothesis}) \)
   \( [\mathcal{E}_1, S; S_1](\eta[X := \sigma(F_1)]) = [\mathcal{E}_2, S; S_2](\eta[X := \sigma(F_2)]) \)
4. \( \Rightarrow (\text{definition}) \)
   \( [\mathcal{E}_1, \sigma X; S; S_1](\eta) = [\mathcal{E}_2, \sigma X; S; S_2](\eta) \)

Remarkably, right-congruence doesn’t hold in general. Corollary 5.5 will state a sufficient condition for right-congruence.

### 3.3. The Dependency Graph between Variables.

Since we introduced a semantic notion of equations, avoiding syntactic expressions, we also need a semantic notion of dependence between variables. Given \( V_1, V_2 \subseteq X \), we define that \( V_1 \) is **independent** of \( V_2 \) with respect to \( \mathcal{E} \), notation \( \text{indep}(\mathcal{E}, V_1, V_2) \), as follows:

\[
\forall \eta_1, \eta_2. (\eta_1 \stackrel{\mathcal{E}}{\equiv} \eta_2) \Rightarrow (\mathcal{E}(\eta_1) \stackrel{V_2}{\equiv} \mathcal{E}(\eta_2))
\]

That is: the solution of variables \( X \in V_1 \) is the same for all those \( \eta \) that differ at most on the values assigned to \( Y \in V_2 \). This is slightly more liberal than the usual syntactic requirement that \( Y \) *doesn’t occur syntactically* in \( \mathcal{E}_X \). We overload the definition of \( \text{indep} \) for individual variables and specifications (and any combination of those), e.g., \( \text{indep}(\mathcal{E}, S_1, S_2) = \text{indep}(\mathcal{E}, \text{dom}(S_1), \text{dom}(S_2)) \) and \( \text{indep}(\mathcal{E}, X, Y) = \text{indep}(\mathcal{E}, \{X\}, \{Y\}) \).

This notion gives rise to the **variable dependency graph** of a FES \( (\mathcal{E}, S) \). The variables in \( \text{dom}(S) \) form the nodes of this graph; the edges \( X \xrightarrow{\mathcal{E}, S} Y \) are defined as \( \neg\text{indep}(\mathcal{E}, X, Y) \). We define \( X \text{ depends (indirectly) on } Y \) (written \( X \xrightarrow{\mathcal{E}, S} Y \)) as the reflexive, transitive closure of \( \xrightarrow{\mathcal{E}, S} \). In other words, there exists a path in the dependency graph from \( X \) to \( Y \). We also use the notation \( X \xrightarrow{\mathcal{E}, S^+} Y \) to denote the transitive closure of \( \xrightarrow{\mathcal{E}, S} \), i.e. there is a **non-empty**
path from \(X\) to \(Y\) in the dependency graph. We assume that \(\text{indep}(\mathcal{E}, X, Y)\) is decidable for all \(\mathcal{E}, X\) and \(Y\). Since \(\text{dom}(\mathcal{S})\) is finite, this also makes \(\mathcal{E} \xrightarrow{\mathcal{S}}\) and \(\mathcal{E} \xrightarrow{\mathcal{S}+}\) decidable.

4. Substituting in FES Equations

In this section, we define two substitution operations on the equations of a FES, and study under which conditions these operations preserve solutions. The first operation allows substituting variables by their definition. We show that this substitution preserves solutions in some new cases (cf. Section 7). The second operation replaces a variable in an equation by its solution.

4.1. Unfolding Definitions. We define \(\text{unfold}(\mathcal{E}, X, Y)\), where each occurrence of \(Y\) in the definition of \(X\) is replaced by the definition of \(Y\), as follows:

\[
\text{unfold}(\mathcal{E}, X, Y)(\eta) := \mathcal{E}(\eta)[X := \mathcal{E}_X(\eta[X := \mathcal{E}Y(\eta)])]
\]

We will use the following observation several times. It basically states that unfolding \(Y\) in \(X\) doesn’t affect other equations than that for \(X\).

**Lemma 4.1.** If \(X \notin \text{dom}(\mathcal{S})\), then

1. \(\text{unfold}(\mathcal{E}, X, Y) \preceq \mathcal{E}\)
2. \([\text{unfold}(\mathcal{E}, X, Y), \mathcal{S}] = [\mathcal{E}, \mathcal{S}]\)

**Proof.** (1) holds by definition of \(\text{unfold}\), as it only modifies the value of \(\mathcal{E}\) on variable \(X\). Then (2) holds by Lemma 3.7.2. \(\square\)

It is known (cf. Example 7.1) that in general one should not unfold \(Y\) in \(X\), if \(Y\) precedes \(X\) in the specification. As a new result we show that we can substitute \(X\) in its own definition:

**Lemma 4.2.** Let \(\mathcal{E} \in \text{Eqs}\) be monotonic. Let \(\mathcal{S} = \sigma_X; \mathcal{S}_1\), and \(X \notin \text{dom}(\mathcal{S}_1)\). Then \([\text{unfold}(\mathcal{E}, X, X), \mathcal{S}] = [\mathcal{E}, \mathcal{S}]\).

**Proof.** For arbitrary \(\eta\), define

\[
F(P) := \mathcal{E}_X([\mathcal{E}, \mathcal{S}_1](\eta[X := P]))
\]

\[
G(P) := \text{unfold}(\mathcal{E}, X, X)([[\mathcal{E}, \mathcal{S}_1](\eta[X := P])])
\]

\[
H(P, Q) := \mathcal{E}_X([[\mathcal{E}, \mathcal{S}_1](\eta[X := P])][X := Q])
\]

By Lemma 3.7.1 and \(X \notin \text{dom}(\mathcal{S}_1)\), we obtain: \([\mathcal{E}, \mathcal{S}_1](\eta[X := P])(X) = \eta[X := P](X) = P\), so

\[
[[\mathcal{E}, \mathcal{S}_1](\eta[X := P])][X := P] = [[\mathcal{E}, \mathcal{S}_1](\eta[X := P])] (*)
\]

Next, we prove that \(\sigma(F) = \sigma(G)\):

\[
\sigma P. G(P)
\]

= (by definition of \(\text{unfold}\))

\[
\sigma P. \mathcal{E}_X([\mathcal{E}, \mathcal{S}_1](\eta[X := P])][X := \mathcal{E}_X([\mathcal{E}, \mathcal{S}_1](\eta[X := P])])
\]

= (by * above)
\[
\sigma P. \mathcal{E}_X \left( \left[ \left. \mathcal{E}, S_1 \right| (\eta | X := P) \right| \right] \left[ X := \mathcal{E}_X \left( \left[ \left. \mathcal{E}, S_1 \right| (\eta | X := P) \right| X := P \right| \right) \right] \right) \\
= \sigma P. H(P, H(P, P)) \\
= \text{(unfold rule, Lemma 2.1.7)} \\
\sigma P. H(P, P) \\
= \text{(by * above)} \\
\sigma P. F(P)
\]

We can now finish the proof:

\[
\left[ \text{unfold}(\mathcal{E}, X, X), \sigma X; S_1 \right](\eta) \\
= \text{(by definition and Lemma 4.1.2)} \\
\left[ \mathcal{E}, S_1 \right](\eta | X := \sigma(G)) \\
= \text{(by the computation before)} \\
\left[ \mathcal{E}, S_1 \right](\eta | X := \sigma(F)) \\
= \text{(by definition)} \\
\left[ \mathcal{E}, \sigma X; S_1 \right](\eta)
\]

The full theorem allows to unfold \( Y \) in the equations for those \( X \) that precede that of \( Y \), and in the equation of \( Y \) itself. So in particular, the case \( X = Y \) is allowed.

**Theorem 4.3.** Let \( \mathcal{E} \in \mathcal{Eqs} \) be monotonic. Let \( S = S_1; \sigma Y; S_2 \) and \( X \notin \text{dom}(S_2) \). Then \( \left[ \text{unfold}(\mathcal{E}, X, Y), S \right] = \left[ \mathcal{E}, S \right] \).

**Proof.** The proof is by induction on \( S_1 \). The base case is \( S_1 = \varepsilon \). If \( X = Y \), we have to prove \( \left[ \text{unfold}(\mathcal{E}, X, X), \sigma X; S_2 \right] = \left[ \mathcal{E}, \sigma X; S_2 \right] \), which is just Lemma 4.2. Otherwise, if \( X \neq Y \), then \( X \notin \text{dom}(\sigma Y; S_2) \), so by Lemma 4.1 \( \left[ \text{unfold}(\mathcal{E}, X, Y), \sigma Y; S_2 \right] = \left[ \mathcal{E}, \sigma Y; S_2 \right] \).

Next, for \( S = \rho Z; S_1; \sigma Y; S_2 \), define \( S_3 := S_1; \sigma Y; S_2 \), and assume the induction hypothesis, \( \left[ \text{unfold}(\mathcal{E}, X, Y), S_3 \right] = \left[ \mathcal{E}, S_3 \right] \).

If \( Z \neq X \), then \( \mathcal{E} \{\subseteq\} \text{unfold}(\mathcal{E}, X, Y) \). From the induction hypothesis, it follows by congruence (Lemma 3.9) that \( \left[ \text{unfold}(\mathcal{E}, X, Y), \rho Z; S_3 \right] = \left[ \mathcal{E}, \rho Z; S_3 \right] \).

If \( Z = X \), we compute for arbitrary \( \eta \in \text{Val} \):

\[
\left[ \text{unfold}(\mathcal{E}, X, Y), \sigma X; S_3 \right](\eta) \\
= \text{(by definition of the semantics)} \\
\left[ \text{unfold}(\mathcal{E}, X, Y), S_3 \right](\eta | X := \sigma(F)) \text{, where} \\
F(P) := \text{unfold}(\mathcal{E}, X, Y)_X \left( \left[ \text{unfold}(\mathcal{E}, X, Y), S_3 \right](\eta | X := P) \right) \\
= \text{(by induction hypothesis)} \\
\left[ \mathcal{E}, S_3 \right](\eta | X := \sigma(F)) \text{, where}
\]
\[ F(P) := \text{unfold}(\mathcal{E}, X, Y)(\mathcal{E}[X := P]) \]
\[ = (\text{definition unfold}) \]
\[ \mathcal{E}_Y(\mathcal{E}[X := P]) \]
\[ = (\text{Lemma 3.8; } Y \in \text{dom}(\mathcal{S})) \]
\[ \mathcal{E}_Y(\mathcal{E}[X := P]) \]
\[ = (\text{congruence and extensionality: } \zeta[Y := \zeta(Y)] = \zeta) \]
\[ \mathcal{E}_Y(\mathcal{E}[X := P]) \]
\[ = [\mathcal{E}, \sigma X; \mathcal{S}](\eta) \]

4.2. Substituting a Partial Solution. The following theorem is motivated in [Mad97] as follows. Assume we know by some means the solution \( a \) for a variable \( X \) in \( (\mathcal{E}, \mathcal{S}) \). Then we can replace the definition of \( X \) by simply putting \( X = a \). We simplify the proof in [Mad97], which is based on an infinite series of FESs. Instead, we just use induction on \( \mathcal{S} \) and some properties of complete lattices.

**Theorem 4.4.** Let \( \mathcal{E} \in \mathcal{Eqs} \) be monotonic and let \( a := [\mathcal{E}, \mathcal{S}](\eta)(X) \). Then
\[ [\mathcal{E}, \mathcal{S}](\eta) = [\mathcal{E}[X := a], \mathcal{S}](\eta) \]

**Proof.** We prove the theorem by induction on \( \mathcal{S} \). The base case is trivial, for \( [\mathcal{E}, \varepsilon](\eta) = \eta = [\mathcal{E}[X := a], \varepsilon](\eta) \). For the induction step \( (\sigma Y; \mathcal{S}) \), we need to define the functions \( a, b: \forall \mathcal{E}_Y \rightarrow U \) and \( F, G: U \rightarrow U \) and \( H: (U \times U) \rightarrow U \):
\[
\begin{align*}
a(\eta') & := [\mathcal{E}, \mathcal{S}](\eta')(X) \\
b(\eta) & := [\mathcal{E}, \sigma Y; \mathcal{S}](\eta)(X) \\
F(P) & := \mathcal{E}_Y([\mathcal{E}, \mathcal{S}](\eta[Y := P])) \\
G(P) & := \mathcal{E}_Y([\mathcal{E}[X := b(\eta)], \mathcal{S}]) \\
H(P, Q) & := \mathcal{E}_Y([\mathcal{E}[X := a(\eta[Y := P])], \mathcal{S}](\eta[Y := Q]))
\end{align*}
\]
Then from the induction hypothesis \( \forall \eta'. [\mathcal{E}, \mathcal{S}](\eta') = [\mathcal{E}[X := a(\eta')], \mathcal{S}](\eta') \), we must prove:
\[ \forall \eta. [\mathcal{E}, \sigma Y; \mathcal{S}](\eta) = [\mathcal{E}[X := b(\eta)], \sigma Y; \mathcal{S}](\eta) \]

We distinguish three cases:
If \( X = Y \) and \( X \notin \text{dom}(\mathcal{S}) \), we compute:
\[
[\mathcal{E}[X := b(\eta)], \sigma X; \mathcal{S}](\eta) = [\mathcal{E}[X := b(\eta)], \mathcal{S}](\eta[X := \sigma P. b(\eta)]) = (\text{by the constant rule, Lemma 2.1.2}) [\mathcal{E}[X := b(\eta)], \mathcal{S}](\eta[X := b(\eta)]) = (\text{by Lemma 3.7.2 and } X \notin \text{dom}(\mathcal{S})) [\mathcal{E}, \mathcal{S}](\eta[X := b(\eta)]) = (\text{unfold definition of } [ ] \text{ in } b(\eta).) [\mathcal{E}, \mathcal{S}](\eta[X := \mathcal{E}[X := \sigma(F)])(\eta)] = (\text{by Lemma 3.7.1 and } X \notin \text{dom}(\mathcal{S})) [\mathcal{E}, \mathcal{S}](\eta[X := \sigma(F)]) = [\mathcal{E}, \sigma X; \mathcal{S}](\eta)
\]
If $X = Y$ and $X \in \text{dom}(S)$, then note that using Lemma 3.7.3, for any $E'$ and appropriate $F'$, we have:

$$\llbracket E', \sigma X; S \rrbracket (\eta) = \llbracket E', S[\eta[X := \sigma F']] \rrbracket = \llbracket E', S \rrbracket (\eta)$$

So in particular, $b(\eta) = a(\eta)$, and we can apply the induction hypothesis: Hence

$$\llbracket E[X \mapsto b(\eta)], \sigma X; S \rrbracket (\eta)$$

= (by the equality above)

$$\llbracket E[X \mapsto a(\eta)], S \rrbracket (\eta)$$

= (induction hypothesis)

$$\llbracket E, S \rrbracket (\eta)$$

= (by the equality above)

$$\llbracket E, \sigma X; S \rrbracket (\eta)$$

Finally, if $X \neq Y$, then we can compute:

$$\llbracket E, \sigma Y; S \rrbracket (\eta)$$

= (induction hypothesis)

$$\llbracket E[X \mapsto a(\eta[Y := \sigma F])], S[\eta[Y := \sigma F]] \rrbracket (\eta)$$

= (unfold definition of $\llbracket \cdot \rrbracket$ in $b(\eta)$.)

$$\llbracket E[X \mapsto b(\eta)], S[\eta[Y := \sigma F]] \rrbracket (\eta)$$

= (will be proved below)

$$\llbracket E[X \mapsto b(\eta)], \sigma Y; S \rrbracket (\eta)$$

= (will be proved below)

$$\llbracket E[X \mapsto b(\eta)], \sigma Y; S \rrbracket (\eta)$$

= (by the equality above)

$$\llbracket E, \sigma X; S \rrbracket (\eta)$$

We must still prove that $\sigma(F) = \sigma(G)$.

$$\sigma P. F(P)$$

= (induction hypothesis)

$$\sigma P. E_F(\llbracket E[X \mapsto a(\eta[Y := P])], S[\eta[Y := P]] \rrbracket)$$

= $\sigma P. H(P, P)$

= Lemma 2.1.8 (solve rule) on $\lambda P.Q. H(Q, P)$

$$\sigma P. H(\sigma P. H(P, P), P)$$

= (as above)

$$\sigma P. H(\sigma P. H(P, P), P)$$

= (unfold definition of $\llbracket \cdot \rrbracket$ in $b$ in $G$)

$$\sigma P. G(P)$$

□
5. Swapping Variables in FES Specifications

We now study swapping the order of variables in a specification. In general, this operation doesn’t exactly preserve solutions. We first show that adjacent variables with the same sign may be swapped without changing the semantics (Section 5.1). Subsequently, we will prove that we can swap the order between blocks of equations, under certain independence criteria (Section 5.2). The main theorem of that section is new (cf. Section 7). Finally, we show that swapping a $\mu/\nu$ sequence by the corresponding $\nu/\mu$ in general leads to a greater or equal solution (Section 5.3).

5.1. Swapping Equations with the same Sign.

Theorem 5.1. Assume $E \in \mathcal{Eqs}$ is monotonic. Then

$$\lfloor E, S_1; \sigma X; \sigma Y; S_2 \rfloor = \lfloor E, S_1; \sigma Y; \sigma X; S_2 \rfloor$$

Proof. We first compute for arbitrary $\eta \in \mathcal{Val}$:

$$\lfloor E, \sigma X; \sigma Y; S_2 \rfloor(\eta)$$

$$= \lfloor E, \sigma Y; S_2 \rfloor(\eta[X := \sigma(F_2)])$$

where

$$F_2(P) = E_X(\lfloor E, \sigma Y; S_2 \rfloor(\eta[X := P]))$$

$$= \lfloor E, S_2 \rfloor(\eta[X := \sigma(F_2), Y := \sigma(F_3)])$$

where

$$F_2(P) = E_X(\lfloor E, \sigma Y; S_2 \rfloor(\eta[X := P]))$$

$$F_3(Q) = E_Y(\lfloor E, S_2 \rfloor(\eta[X := \sigma(F_2), Y := Q]))$$

= (unfold definition of $\lfloor \rfloor$ in $F_2$, introduce $F_1$)

$$\lfloor E, S_2 \rfloor(\eta[X := \sigma(F_2), Y := \sigma(F_3)])$$

where

$$F_1(P)(Q) = E_Y(\lfloor E, S_2 \rfloor(\eta[X := P, Y := Q]))$$

$$F_2(P) = E_X(\lfloor E, S_2 \rfloor(\eta[X := P, Y := \sigma(F_1(P))]))$$

$$F_3(Q) = E_Y(\lfloor E, S_2 \rfloor(\eta[X := \sigma(F_2), Y := Q]))$$

$$= A(\sigma(F_2), \sigma(F_3))$$

Symmetrically, we get:

$$\lfloor E, \sigma Y; \sigma X; S_2 \rfloor(\eta)$$

$$= B(\sigma(G_2), \sigma(G_3))$$

where

$$B(Q, P) = \lfloor E, S_2 \rfloor(\eta[Y := Q, X := P])$$

$$G_1(Q)(P) = E_X(B(Q, P))$$

$$G_2(Q) = E_Y(B(Q, \sigma(G_1(Q))))$$

$$G_3(P) = E_X(B(\sigma(G_2), P))$$
Note that the theorem is trivial when $X = Y$. So we may assume $X \neq Y$. Hence $A(P, Q) = B(Q, P)$, and we have:

\[
\sigma(F_2) = \sigma P. E_X(\sigma P. E_X(A(P, Q), Q))) = B(Q, P)
\]

\[
\sigma P. E_X(B(\sigma Q. E_Y(B(Q, \sigma P. E_X(B(Q, P))))), P)
\]

\[
\sigma P. E_X(B(\sigma Q. E_Y(B(Q, \sigma(G_1(Q)))), P)) = \sigma P. E_X(B(\sigma(G_2), P)) = \sigma(G_3)
\]

We can now finish the proof:

\[
\text{(computation above, and full symmetry)}
\]

\[
\sigma(F_2) = \sigma(G_3) \text{ and } \sigma(F_3) = \sigma(G_2)
\]

\[
\Rightarrow \text{(because } A(P, Q) = B(Q, P) \text{ )}
\]

\[
A(\sigma(F_2), \sigma(F_3)) = B(\sigma(G_2), \sigma(G_3))
\]

\[
\Rightarrow [E, \sigma X; \sigma Y; S_2]\{\eta\} = [E, \sigma Y; \sigma X; S_2]\{\eta\}
\]

\[
\Rightarrow \text{(Lemma 3.9)}
\]

\[
[E, S_1; \sigma X; \sigma Y; S_2]\{\eta\} = [E, S_1; \sigma Y; \sigma X; S_2]\{\eta\}
\]

5.2. Migrating Independent Blocks of Equations. Our aim here is to investigate swapping blocks of equations that are independent. We first need two technical lemmas. The first lemma enables to commute updates to valuations with computing solutions:

**Lemma 5.2.** If $X \notin \text{dom}(S)$ and indep($E, S, X$), then

\[
[E, S]\{\eta[X := P]\} = ([E, S]\{\eta\})[X := P]
\]

**Proof.** Induction on $S$. The base case is trivial:

\[
[E, \varepsilon]\{\eta[X := P]\} = \eta[X := P] = [E, \varepsilon]\{\eta\}[X := P]
\]

Case $S = \sigma Y; S_1$. Assume $X \notin \text{dom}(S)$ and indep($E, S, X$), then $X \neq Y$, and also $X \notin \text{dom}(S_1)$ and indep($E, S_1, X$), so the induction hypothesis can be applied. Then

\[
[E, \sigma Y; S_1]\{\eta[X := P]\} = [E, S_1]\{\eta[X := P, Y := \sigma(F)]\},
\]
we can use the induction hypothesis. Define:

\[ F(Q) := \mathcal{E}_Y(\llbracket \mathcal{E}, \mathcal{S}_1 \rrbracket(\eta[X := P, Y := Q])) \]
\[ = (\text{induction hypothesis, and } X \neq Y) \]
\[ \mathcal{E}_Y(\llbracket \mathcal{E}, \mathcal{S}_1 \rrbracket(\eta[Y := Q])[X := P]) \]
\[ = (Y \in \text{dom}(\mathcal{S}) \text{ is independent of } X) \]
\[ \mathcal{E}_Y(\llbracket \mathcal{E}, \mathcal{S}_1 \rrbracket(\eta[Y := Q])) \]
\[ = G(Q) \]
\[ = \llbracket \mathcal{E}, \mathcal{S}_1 \rrbracket(\eta[X := P, Y := \sigma(G)]) \]
\[ = (\text{induction hypothesis, and } X \neq Y) \]
\[ \llbracket \mathcal{E}, \mathcal{S}_1 \rrbracket(\eta[Y := \sigma(G)][X := P]) \]
\[ = \llbracket \mathcal{E}, \sigma Y; \mathcal{S}_1 \rrbracket(\eta[X := P]) \] \[ \square \]

The next lemma states that independent specifications can be solved independently.

**Lemma 5.3.** Let \( \mathcal{E} \in \mathcal{Eqs} \) and \( \mathcal{S}_1, \mathcal{S}_2 \in \text{Spec} \). If \( \text{indep}(\mathcal{E}, \mathcal{S}_1, \mathcal{S}_2) \), then for all \( \eta \in \text{Val}, \llbracket \mathcal{E}, \mathcal{S}_1; \mathcal{S}_2 \rrbracket(\eta) = \llbracket \mathcal{E}, \mathcal{S}_2 \rrbracket(\llbracket \mathcal{E}, \mathcal{S}_1 \rrbracket(\eta)) \).

**Proof.** Induction on \( \mathcal{S}_1 \). In case \( \mathcal{S}_1 = \varepsilon \) we obtain indeed:

\[ \llbracket \mathcal{E}, \varepsilon; \mathcal{S}_2 \rrbracket(\eta) = \llbracket \mathcal{E}, \mathcal{S}_2 \rrbracket(\eta) = \llbracket \mathcal{E}, \mathcal{S}_2 \rrbracket(\llbracket \mathcal{E}, \varepsilon \rrbracket(\eta)) \]

Next, consider \( \mathcal{S}_1 = \sigma X; \mathcal{S} \). Assume \( \text{indep}(\mathcal{E}, \mathcal{S}_1, \mathcal{S}_2) \), then it follows that \( \text{indep}(\mathcal{E}, \mathcal{S}, \mathcal{S}_2) \), so we can use the induction hypothesis. Define:

\[ F(P) := \mathcal{E}_X(\llbracket \mathcal{E}, \sigma X; \mathcal{S}_2 \rrbracket(\eta[X := P])) \]
\[ G(P) := \mathcal{E}_X(\llbracket \mathcal{E}, \mathcal{S} \rrbracket(\eta[X := P])) \]

In order to show that \( F = G \), it suffices (because \( \mathcal{E}_X \) is independent of \( \mathcal{S}_2 \)) to show that for any \( P \in U \) and \( Y \notin \text{dom}(\mathcal{S}_2) \):

\[ \llbracket \mathcal{E}, \mathcal{S}; \mathcal{S}_2 \rrbracket(\eta[X := P])(Y) \]
\[ = (\text{induction hypothesis}) \]
\[ \llbracket \mathcal{E}, \mathcal{S}_2 \rrbracket(\llbracket \mathcal{E}, \mathcal{S} \rrbracket(\eta[X := P]))(Y) \]
\[ = (\text{Lemma } 3.7.1) \]
\[ \llbracket \mathcal{E}, \mathcal{S} \rrbracket(\eta[X := P])(Y) \]

Next, we finish the proof with the following calculation:

\[ \llbracket \mathcal{E}, \sigma X; \mathcal{S}; \mathcal{S}_2 \rrbracket(\eta) \]
\[ = \llbracket \mathcal{E}, \mathcal{S}; \mathcal{S}_2 \rrbracket(\eta[X := \sigma(F)]) \]
\[ = (\text{induction hypothesis}) \]
\[ \llbracket \mathcal{E}, \mathcal{S}_2 \rrbracket(\llbracket \mathcal{E}, \mathcal{S} \rrbracket(\eta[X := \sigma(F)])) \]
\[ = (F = G, \text{ see above}) \]
\[ \llbracket \mathcal{E}, \mathcal{S}_2 \rrbracket(\llbracket \mathcal{E}, \mathcal{S} \rrbracket(\eta[X := \sigma(G)])) \]
\[ = \llbracket \mathcal{E}, \sigma X; \mathcal{S} \rrbracket(\eta) \] \[ \square \]

The next theorem shows that two disjoint blocks of equations can be swapped, provided one of them doesn’t depend on the other. Note that a dependence in one direction is allowed,
and that it doesn’t matter in which direction by symmetry. Theorem 5.7 will generalize this by adding left- and right-contexts under certain conditions.

**Theorem 5.4.** Let disjoint$({S}_1, {S}_2)$ and indep$({E}, {S}_1, {S}_2)$. Then $[{E}, {S}_1; {S}_2] = [{E}, {S}_2; {S}_1]$.

**Proof.** Induction on $S_2$. The base case is trivial. For the induction step, let $S_2 = \sigma X; S$. If we assume disjoint$({S}_1, {S}_2)$ and indep$({E}, {S}_1, {S}_2)$, then we also obtain disjoint$({S}, S_1)$ and indep$({E}, S_1, S)$, so we may apply the induction hypothesis $[{E}, S_1; S] = [{E}, S; S_1]$. Furthermore, from the same assumptions, we also get $X \notin \text{dom}(S_1)$ and indep$({E}, S_1, X)$. Let $\eta$ be arbitrary.

$$
[e, s_1; \sigma X; s](\eta)
= (\text{Lemma 5.3})
= [e, s][e, s_1](\eta)\left[X := \sigma(F)\right],
$$

where $F(P) := E_X([e, s][e, s_1](\eta)[X := P]) = (\text{Lemma 5.2})$.

$$
E_X([e, s][e, s_1](\eta)[X := P]) = (\text{Lemma 5.3})
= E_X([e, s_1; s](\eta[X := P]))
= : G(P)
$$

Further, from the same assumptions, we also get $X \notin \text{dom}(S_1)$ and indep$({E}, S_1, X)$. Let $\eta$ be arbitrary.

$$
[e, s_1; \sigma X; s](\eta)
= (\text{Lemma 5.3})
= [e, s][e, s_1](\eta)\left[X := \sigma(G)\right],
$$

where $F(P) := E_X([e, s][e, s_1](\eta)[X := G]) = (\text{Lemma 5.2})$.

$$
E_X([e, s][e, s_1](\eta)[X := G]) = (\text{Lemma 5.3})
= E_X([e, s_1; s](\eta[X := G]))
= [e, s_1; s](\eta)
= (\text{Lemma 3.9 and induction hypothesis})
= [e, s; s_1](\eta).
$$

This migration theorem has several interesting corollaries. First, we get right-congruence for independent specifications.

**Corollary 5.5.** Assume that indep$({E}_1, S_1, S)$, indep$({E}_2, S_2, S)$, disjoint$({S}, S_1; S_2)$ and that $E_1 \subseteq E_2$. Then $[E_1, S_1] = [E_2, S_2]$ implies $[E_1, S_1; S] = [E_2, S_2; S]$.

We also get the near-reverse of Lemma 5.3:

**Corollary 5.6.** Let indep$({E}, S_2, S_1)$ and disjoint$({S}_1, S_2)$. Then for all $\eta \in \text{Val}$, we have $[E, S_2; S_1](\eta) = [E, S_1][E, S_2](\eta)$.

**Proof.** Under the given assumptions, we obtain from Theorem 5.4 (applied from right to left) and Lemma 5.3:

$$
[e, s_1; s_2](\eta) = [e, s_2; s_1](\eta) = [e, s_1][e, s_2](\eta).
$$

**Theorem 5.7.** Assume that disjoint$({S}_1, {S}_2; S_3)$. Also, assume that either indep$({E}, S_1, S_2; S_3)$, or indep$({E}, S_2; S_3, S_1)$. Then $[E, S_0; S_1; S_2; S_3] = [E, S_0; S_2; S_1; S_3]$. 

\[\square\]
Proof. We also have disjoint($S_1, S_3$), and either indep($E, S_1, S_3$) or indep($E, S_3, S_1$). Using Lemma 3.9 and Theorem 5.4 twice (in either direction) we get:

$$[E, S_0; S_1; S_2; S_3] = [E, S_0; S_2; S_3; S_1] = [E, S_0; S_2; S_1; S_3]$$

5.3. **Inequalities by Swapping or Changing Signs.** In this section, we will prove a few inequalities. Theorem 5.9 shows the consequence of swapping variables with a different sign; Theorem 5.10 shows the effect of changing the sign of a variable. But first, it will be shown that $\leq$ is a left congruence:

**Lemma 5.8.** Let $E_1, E_2 \in Eqs$ and $S, S_1, S_2 \in Spec$. If $E_1$ is monotonic, $E_1 \subseteq E_2$, and $[E_1, S_1] \leq [E_2, S_2]$, then $[E_1, S_1] \leq [E_2, S_2]$.

**Proof.** Induction on $S$. The base case is trivial.

$$[E_1, \sigma X; S; S_1](\eta) = [E_1, S; S_1](\eta[X := \sigma(F)])$$

where

$$F(P) := E_1, X([E_1, S; S_1](\eta[X := F(P)])$$

$$\leq$$ (by induction hypothesis and $E_1$ monotonic)

$$E_1, X([E_2, S; S_2](\eta[X := P]))$$

$$= E_2, X([E_2, S; S_2](\eta[X := P]))$$

$$=: G(P)$$

$$\leq$$ (Using Lemma 3.6.1)

$$[E_1, S; S_1](\eta[X := \sigma(G)])$$

$$\leq$$ (by induction hypothesis)

$$[E_2, S; S_2](\eta[X := \sigma(G)])$$

$$= [E_2, \sigma X; S; S_2](\eta)$$

Note that, by duality, the above lemma may also be applied if $E_2$ is monotonic instead of $E_1$. Moreover, note that (only) for monotonic $E_1$, Lemma 3.9 would follow from Lemma 5.8.

**Theorem 5.9.** Assume $E \in Eqs$ is monotonic and $X \neq Y$. Then

$$[E, S_1; \mu X; \nu Y; S_2] \leq [E, S_1; \nu Y; \mu X; S_2]$$

**Proof.** As in Theorem 5.1, and using $X \neq Y$, we obtain:

$$[E, \mu X; \nu Y; S_2](\eta) = A(\mu(F_2), \nu(F_3))$$

where

$$A(P, Q) = [E, S_2](\eta[X := P, Y := Q])$$

$$F_1(P)(Q) = E_Y(A(P, Q))$$

$$F_2(P) = E_X(A(P, \nu(F_1(P))))$$

$$F_3(Q) = E_Y(A(\mu(F_2), Q))$$

$$[E, \nu Y; \mu X; S_2](\eta) = A(\mu(G_3), \nu(G_2))$$

where

$$G_1(Q)(P) = E_X(A(P, Q))$$

$$G_2(Q) = E_Y(A(\mu(G_1(Q)), Q))$$

$$G_3(P) = E_X(A(P, \nu(G_2)))$$
By Lemma 2.2.4(a), \( \mu(F_2) \leq \mu(G_3) \), and by Lemma 2.2.4(b), \( \nu(F_3) \leq \nu(G_2) \), whence it follows that \( [\mathcal{E}, \mu X; \nu Y; \mathcal{S}_2](\eta) \leq [\mathcal{E}, \nu Y; \mu X; \mathcal{S}_2](\eta) \). The theorem then follows by Lemma 5.8. \( \Box \)

We end this section with another inequality:

**Theorem 5.10.** If \( \mathcal{E} \) is monotonic, then \( [\mathcal{E}, \mathcal{S}_1; \mu X; \mathcal{S}_2] \leq [\mathcal{E}, \mathcal{S}_1; \nu X; \mathcal{S}_2] \).

**Proof.** Let \( \eta \) be an arbitrary valuation, and define \( F : U \to U \) by \( F(P) := \mathcal{E}_X([\mathcal{E}, \mathcal{S}_2](\eta[X := P])) \). We then have:

\[
\begin{align*}
(\text{Theorem 2.2.1}) & \quad \mu P, F(P) \leq \nu P, F(P) \\
\Rightarrow (\text{Monotonicity, Theorem 3.6.1}) & \quad [\mathcal{E}, \mathcal{S}_2](\eta[X := \mu P, F(P)]) \leq [\mathcal{E}, \mathcal{S}_2](\eta[X := \nu P, F(P)]) \\
\Rightarrow (\text{Definition semantics}) & \quad [\mathcal{E}, \mu X; \mathcal{S}](\eta) \leq [\mathcal{E}, \nu X; \mathcal{S}_2](\eta) \\
\Rightarrow (\eta \text{ was arbitrary}) & \quad [\mathcal{E}, \mu X; \mathcal{S}] \leq [\mathcal{E}, \nu X; \mathcal{S}_2] \\
\Rightarrow (\text{Congruence, Theorem 5.8}) & \quad [\mathcal{E}, \mathcal{S}_1; \mu X; \mathcal{S}_2] \leq [\mathcal{E}, \mathcal{S}_1; \nu X; \mathcal{S}_2] \quad \Box
\end{align*}
\]

In the next section, we will see sufficient conditions under which the inequality signs of these theorems can be turned into equalities. These conditions will be phrased in terms of the dependency graph.

### 6. Indirect Dependencies and Loops

In Section 5.2, we studied direct dependencies between variables. Basically, a direct dependency of \( X \) on \( Y \) means that \( Y \) occurs in the definition of \( X \). We will now study the effect of indirect dependencies, written \( X \overset{\mathcal{E}, \mathcal{S}}{\rightarrow} Y \) (cf. the definitions in Section 3.3)

Given a specification \( \mathcal{S} \) and a computable predicate \( f \) on variables, we define \( \text{split}_f(\mathcal{S}) = (\mathcal{S}_1, \mathcal{S}_2) \), where \( \mathcal{S}_1 \) is the sublist of \( \mathcal{S} \) with those \( X \) for which \( f(X) \) does not hold and \( \mathcal{S}_2 \) is the sublist of \( \mathcal{S} \) with those \( X \) for which \( f(X) \) does hold. Notice that, within \( \mathcal{S}_1 \) and \( \mathcal{S}_2 \), variables keep their order from \( \mathcal{S} \).

The following basic facts follow directly from the definition of \( \text{split} \).

**Lemma 6.1.** Let \( \text{split}_f(\mathcal{S}) = (\mathcal{S}_1, \mathcal{S}_2) \), then \( \text{dom}(\mathcal{S}) = \text{dom}(\mathcal{S}_1) \cup \text{dom}(\mathcal{S}_2) \) and \( \text{disjoint}(\mathcal{S}_1, \mathcal{S}_2) \).

We first show how the equations in a FES may be rearranged if the specification is split in such a way that certain independence conditions are fulfilled.

**Lemma 6.2.** Let \( f \) be a predicate and \( \mathcal{S} \) a specification such that \( \text{split}_f(\mathcal{S}) = (\mathcal{S}_1, \mathcal{S}_2) \) and \( \text{indep}(\mathcal{E}, \mathcal{S}_2, \mathcal{S}_1) \). Then \( [\mathcal{E}, \mathcal{S}] = [\mathcal{E}, \mathcal{S}_1; \mathcal{S}_2] \).

**Proof.** We perform induction on \( \mathcal{S} \). The base case is trivial. Let \( \text{split}_f(\mathcal{S}) = (\mathcal{S}_1, \mathcal{S}_2) \) and assume as induction hypothesis that \( \text{indep}(\mathcal{E}, \mathcal{S}_2, \mathcal{S}_1) \) implies \( [\mathcal{E}, \mathcal{S}] = [\mathcal{E}, \mathcal{S}_1; \mathcal{S}_2] \). For the induction step, we consider the specification \( \sigma Y; \mathcal{S} \) and distinguish two cases.
If \( f(Y) \) does not hold, then we have \( \text{split}_f(\sigma Y; \mathcal{S}) = (\sigma Y; \mathcal{S}_1, \mathcal{S}_2) \). Accordingly, we assume \( \text{indep}(\mathcal{E}, \sigma Y; \mathcal{S}_2, \mathcal{S}_1) \), which implies \( \text{indep}(\mathcal{E}, \mathcal{S}_2, \mathcal{S}_1) \). We can thus apply the induction hypothesis and congruence (Lemma 3.9) to obtain \( [\mathcal{E}, \sigma Y; \mathcal{S}] = [\mathcal{E}, \sigma Y; \mathcal{S}_1; \mathcal{S}_2] \).

Otherwise, if \( f(Y) \) holds, we obtain \( \text{split}_f(\sigma Y; \mathcal{S}) = (\mathcal{S}_1, \sigma Y; \mathcal{S}_2) \). Now we assume that \( \text{indep}(\mathcal{E}, \mathcal{S}_2, \sigma Y; \mathcal{S}_1) \), which again implies \( \text{indep}(\mathcal{E}, \mathcal{S}_2, \mathcal{S}_1) \). We also have \( \text{disjoint}(\mathcal{S}_1, \sigma Y; \mathcal{S}_2) \) (Lemma 6.1), so we may apply Theorem 5.7 below:

\[
[\mathcal{E}, \sigma Y; \mathcal{S}]
= (\text{by induction hypothesis and Lemma 3.9})
[\mathcal{E}, \sigma Y; \mathcal{S}_1; \mathcal{S}_2]
= (\text{by Theorem 5.7})
[\mathcal{E}, \mathcal{S}_1; \sigma Y; \mathcal{S}_2]
\]

We simplify notation and write \( \text{split}_{X, \mathcal{E}}(\mathcal{S}) \) for \( \text{split}_{\text{dep}_{X, \mathcal{E}}} \mathcal{S}(\mathcal{S}) \), defining the predicate \( \text{dep}_{X, \mathcal{E}} Y = X \xrightarrow{\mathcal{E}} Y \). If \( \text{indep}(\mathcal{E}, X, Y) \) is computable (which we assume henceforward), then \( X \xrightarrow{\mathcal{E}} Y \) is also computable since \( \mathcal{S} \) is finite. Intuitively, if \( \text{split}_{X, \mathcal{E}}(\mathcal{S}) = (\mathcal{S}_1, \mathcal{S}_2) \), then \( \mathcal{S}_1 \) is the sublist of \( \mathcal{S} \) with those \( Y \) on which \( X \) does not depend indirectly; and \( \mathcal{S}_2 \) is the sublist of \( \mathcal{S} \) with those \( Z \) on which \( X \) does depend indirectly. Notice that, if \( X \notin \text{dom}(\mathcal{S}) \), then \( \text{split}_{X, \mathcal{E}}(\mathcal{S}) = (\mathcal{S}, \varepsilon) \).

We have the following lemma about splitting a specification based on the dependencies of \( X \):

**Lemma 6.3.** If \( \text{split}_{X, \mathcal{E}}(\mathcal{S}) = (\mathcal{S}_1, \mathcal{S}_2) \), then \( \text{indep}(\mathcal{E}, \mathcal{S}_2, \mathcal{S}_1) \).

**Proof.** Assume that some \( Z \in \text{dom}(\mathcal{S}_2) \) would use some \( Y \in \text{dom}(\mathcal{S}_1) \) in its definition in \( \mathcal{E} \). Then \( X \xrightarrow{\mathcal{E}} Z \xrightarrow{\mathcal{E}} Y \), so \( X \xrightarrow{\mathcal{E}} Y \), and \( Y \) would be in \( \mathcal{S}_2 \) and not in \( \mathcal{S}_1 \). □

The key theorem of this section states that the equations in a FES can be rearranged, such that all equations that \( X \) depends on precede all other equations, or vice versa. This is useful, because those parts can be solved independently, using Lemma 5.3. By repeatedly picking a variable in a terminal strongly connected component of the remaining variable dependency graph, one can thus solve all SCCs one by one. This idea already appeared in [Jur00] for parity games, although it does not always provide performance benefits in practice [FL09]. The theorem may also be used to reduce the number of fixpoint alternations in a FES.

**Theorem 6.4.** Let \( \text{split}_{X, \mathcal{E}}(\mathcal{S}) = (\mathcal{S}_1, \mathcal{S}_2) \). Then \( [\mathcal{E}, \mathcal{S}] = [\mathcal{E}, \mathcal{S}_1; \mathcal{S}_2] = [\mathcal{E}, \mathcal{S}_2; \mathcal{S}_1] \).

**Proof.** The first equality follows from Lemmas 6.2 and 6.3. From Theorem 5.4 and Lemmas 6.1 and 6.3 it follows that also \( [\mathcal{E}, \mathcal{S}_1; \mathcal{S}_2] = [\mathcal{E}, \mathcal{S}_2; \mathcal{S}_1] \). □

Based on this reordering principle, we can prove three more interesting results, which we will do in the next subsections.

### 6.1. Swapping Signs and Dependency Loops

The first result (Theorem 6.7) states that the sign of a variable \( X \) is only relevant if it depends on itself, i.e., \( X \) is on a cycle in \( \mathcal{X} \mathcal{S}_2^+ \) (recall that \( \mathcal{X} \mathcal{S}_2^+ \) indicates a non-empty path in the variable dependency graph). We first need a couple of auxiliary lemmas:
Lemma 6.5. If \( X \notin \text{dom}(\mathcal{S}) \) and we have \( \text{indep}(\mathcal{E}, \mathcal{S}, X) \) as well as \( \text{indep}(\mathcal{E}, X, X) \), then \( [\mathcal{E}, \mu X; \mathcal{S}] = [\mathcal{E}, \nu X; \mathcal{S}] \).

Proof. For \( \sigma \in \{\mu, \nu\} \) and arbitrary valuation \( \eta \), we have:

\[
[\mathcal{E}, \sigma X; \mathcal{S}] (\eta) = (\text{by definition of semantics})
[\mathcal{E}, \mathcal{S}] (\eta[X := \sigma(F)])
\]

where \( F(P) := \mathcal{E}_X([[\mathcal{E}, \mathcal{S}] (\eta[X := P])]) \)

\[
= (\text{Lemma 5.2, and } X \notin \text{dom}(\mathcal{S}) \text{ and } \text{indep}(\mathcal{E}, \mathcal{S}, X))
\]

\[
\mathcal{E}_X([[\mathcal{E}, \mathcal{S}] \eta][X := P])
\]

\[
= (\text{by definition of } \text{indep}(\mathcal{E}, X, X))
\]

\[
\mathcal{E}_X([[\mathcal{E}, \mathcal{S}] \eta])
\]

\[
= (\text{constant rule, Lemma 2.1.2})
[\mathcal{E}, \mathcal{S}] (\eta[X := \mathcal{E}_X([[\mathcal{E}, \mathcal{S}] \eta])])
\]

So indeed \([\mathcal{E}, \mu X; \mathcal{S}] = [\mathcal{E}, \nu X; \mathcal{S}] \). \( \square \)

Lemma 6.6. If not \( X \xrightarrow{\mathcal{E}, \mu X; \mathcal{S}} X \), and \( X \notin \text{dom}(\mathcal{S}) \), then \([\mathcal{E}, \mu X; \mathcal{S}] = [\mathcal{E}, \nu X; \mathcal{S}] \).

Proof. Let \( \mathcal{S}_1 \) and \( \mathcal{S}_2 \) be such that \( \text{split}_{\mathcal{E}, \mathcal{S}}(\sigma X; \mathcal{S}) = (\mathcal{S}_1, \sigma X; \mathcal{S}_2) \), for \( \sigma \in \{\mu, \nu\} \). Note that if not \( \text{indep}(\mathcal{E}, \mu X; \mathcal{S}_2, X) \), then for some \( Y \in \text{dom}(\mu X; \mathcal{S}_2) \), by definition of \( \text{split} \), \( X \xrightarrow{\mathcal{E}, \mu X; \mathcal{S}_2} Y \xrightarrow{\mathcal{E}} X \), which contradicts the assumption not \( X \xrightarrow{\mathcal{E}, \mu X; \mathcal{S}} X \). From \( \text{dom}(\mathcal{S}_2) \subseteq \text{dom}(\mathcal{S}) \), we obtain \( X \notin \text{dom}(\mathcal{S}_2) \). Hence, \( X \notin \text{dom}(\mathcal{S}_2) \) and \( \text{indep}(\mathcal{E}, \mu X; \mathcal{S}_2, X) \), so Lemma 6.5 applies. Together with Theorem 6.4 and Lemma 3.9, we then compute:

\[
[\mathcal{E}, \mu X; \mathcal{S}] = [\mathcal{E}, \mathcal{S}_1; \mu X; \mathcal{S}_2] = [\mathcal{E}, \mathcal{S}_1; \nu X; \mathcal{S}_2] = [\mathcal{E}, \nu X; \mathcal{S}] \quad \square
\]

Intuitively, the sign of \( X \) is only relevant if \( X \) is the most relevant variable (i.e. leftmost in the specification) on some loop in the dependency graph. So in the full theorem, we can restrict to dependencies through variables right from \( X \):

Theorem 6.7. Assume that not \( X \xrightarrow{\mathcal{E}, \mu X; \mathcal{S}_2} X \), and \( X \notin \text{dom}(\mathcal{S}_2) \). Then

\[
[\mathcal{E}, \mathcal{S}_1; \mu X; \mathcal{S}_2] = [\mathcal{E}, \mathcal{S}_1; \nu X; \mathcal{S}_2]
\]

Proof. By Lemma 6.6, \([\mathcal{E}, \mu X; \mathcal{S}_2] = [\mathcal{E}, \nu X; \mathcal{S}_2] \). The result follows by congruence, Lemma 3.9. \( \square \)

6.2. Reordering Variables and Dependency Loops. The second result (Theorem 6.9) allows to swap any two neighbouring variables that don’t occur on a loop in the dependency graph.

Lemma 6.8. Let not \( X \xrightarrow{\mathcal{E}, \sigma X; \rho Y; \mathcal{S}} Y \). Then \([\mathcal{E}, \sigma X; \rho Y; \mathcal{S}] = [\mathcal{E}, \rho Y; \sigma X; \mathcal{S}] \).

Proof. Note that for some \( \mathcal{S}_1 \) and \( \mathcal{S}_2 \), we have

\[
\text{split}_{\mathcal{E}, \mathcal{S}} (\sigma X; \rho Y; \mathcal{S}) = (\rho Y; \mathcal{S}_1, \sigma X; \mathcal{S}_2) = \text{split}_{\mathcal{E}, \mathcal{S}} (\rho Y; \sigma X; \mathcal{S})
\]

Hence, by applying Theorem 6.4 twice, we obtain:

\[
[\mathcal{E}, \sigma X; \rho Y; \mathcal{S}] = [\mathcal{E}, \rho Y; \mathcal{S}_1; \sigma X; \mathcal{S}_2] = [\mathcal{E}, \rho Y; \sigma X; \mathcal{S}] \quad \square
\]
Again, we can strengthen this, by observing that $X$ and $Y$ can be swapped, when there is no loop that has either $X$ or $Y$ as its most relevant variable in the specification:

**Theorem 6.9.** Assume that not $X \xrightarrow{\mathcal{E}, \sigma Y; \rho Y; S_2} Y$. Then we have

$$[\mathcal{E}, S_1; \sigma X; \rho Y; S_2] = [\mathcal{E}, S_1; \rho Y; \sigma X; S_2]$$

**Proof.** By Lemma 6.8, $[\mathcal{E}, \sigma X; \rho Y; S_2] = [\mathcal{E}, \rho Y; \sigma X; S_2]$. The result then follows by congruence, Lemma 3.9. 

Note that this result strengthens Theorem 5.1 (the signs may now be different), Theorem 5.7 (we can have mutual dependencies on $S$, as long as no loop is introduced) and Theorem 5.9 (we have here equality rather than inequality).

### 6.3. Forward Substitution and Dependency Loops.

The final result strengthens Theorem 4.3 by allowing unfolding of $Y$ in the definition of $X$, even if $Y$ precedes $X$ in the specification, provided $Y$ doesn’t depend on $X$:

**Theorem 6.10.** Let $\mathcal{E} \in \mathcal{E}_{qs}$ be monotonic. Let $S = S_1, \sigma Y, S_2$. Assume that not $Y \xrightarrow{\mathcal{E}, S} X$.

**Proof.** Assume not $Y \xrightarrow{\mathcal{E}, S} X$. Then the following two observations hold:

1. for all $Z \in X$, $Y \xrightarrow{\mathcal{E}, S} Z \iff Y \xrightarrow{\text{unfold}(\mathcal{E}, X, Y), S} Z$
2. $\text{split}_Y(\mathcal{E})(S) = \text{split}_{\text{unfold}(\mathcal{E}, X, Y)}(S)$

The first item holds, because $\text{unfold}(\mathcal{E}, X, Y)$ only modifies the definition of $X$, but $Y$ doesn’t refer to it. The second then follows from the definition of $\text{split}$.

Let $(L_1, L_2) := \text{split}_Y(\mathcal{E})(S)$. Then, as $Y \xrightarrow{\mathcal{E}, S} Y$, we have $L_2 = L_3; \sigma Y; L_4$. Note that $X \notin \text{dom}(L_4)$, for we would then have $Y \xrightarrow{\mathcal{E}, S} X$, contradicting the assumptions. Then we can compute:

$$[\mathcal{E}, S] = (\text{Theorem 6.4})$$

$$[\mathcal{E}, L_1; L_3; \sigma Y; L_4] = (\text{Theorem 4.3})$$

$$[\text{unfold}(\mathcal{E}, X, Y), L_1; L_3; \sigma Y; L_4] = (\text{Theorem 6.4, observation (2) above})$$

$$[\text{unfold}(\mathcal{E}, X, Y), S]$$

### 7. Summary – Examples – Related Work

Table 1 summarizes our main results. We will discuss their relevance and compare them to previous work in Section 7.1-7.3. Table 2 contains some other useful facts on FES, discussed in Section 7.4.
7.1. **Substituting Definitions and Solutions.** Theorem 4.3 in this form is new. It generalizes [Mad97, Lemma 6.3] (for BES only) and [GW05a, Lemma 18] (for PBES only) to FES. Another generalization is that we allow that $X = Y$. That is, besides unfolding the $Y$’s in the definition of some $X$ preceding $Y$, one can even unfold $Y$ in its own definition. The proof for this case is more involved (cf. Lemma 4.2). For BES this is useless, but for PBES this is useful, and already used in [OW10, PWW11] to unfold PBESs to BESs. The technique of unfolding PBESs is perhaps the most commonly applied method of solving PBESs [FAAKS24, KFG20, PWW11], although symbolic approaches do exist [KNIU19, NWG20].

Theorem 6.10 is a new result, generalizing the case where $\text{indep}(E, Y, X)$ for all $X$ (i.e. $Y$ is in solved form, [Mad97, GW05a]). In general, one cannot unfold $Y$ in the definition of $X$, when $Y$ precedes $X$. However, if there is no dependency path from $Y$ to $X$, then a forward substitution is allowed. The proof is based on clever reordering of equations. The following example shows that this condition is necessary:

**Example 7.1.** Consider the following two Boolean Equation Systems:

<table>
<thead>
<tr>
<th>$B_1$</th>
<th>$B_2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\nu Y = X$</td>
<td>$\nu Y = X$</td>
</tr>
<tr>
<td>$\mu X = Y$</td>
<td>$\mu X = X$</td>
</tr>
</tbody>
</table>

Unfolding $Y$ in the definition of $X$ in $B_1$ yields $B_2$. However, $B_1$ has the solution $(\top, \top)$, while the solution of $B_2$ is $(\bot, \bot)$. The reader can check this with the method described in Example 7.2.

Theorem 4.4 allows to substitute a partial solution in a FES. It occurs already in [Mad97, Lemma 3.19]. However, our proof is more direct. Mader suggests that a direct inductive argument is not possible, and proves the theorem by contradiction, constructing an infinite set of equation systems. We show that with an appropriate induction loading, the theorem can be reduced to another lemma in fixpoint calculus (Lemma 2.1.8).

The substitution theorems form the basis for solving BES and PBES by Gauss-elimination. They are called the global steps. Besides global steps, one needs local steps, to eliminate $X$ from the right hand side of its own definition. For BES, a local step is trivial, because (only) in the Boolean lattice we have $\mu X.f(X) = f(\bot)$ and $\nu X.f(X) = f(\top)$. Local solution for PBES is much harder, and studied in [GW05a, OW10]. We stress that our results show that the global steps hold in any FES. However, effective local solution is specific to the underlying complete lattice.

**Example 7.2.** The following example shows the solution of a BES by Gauss elimination. Basically, one first substitutes definitions backwards using Theorem 4.3 (along the way, we use the identity $Y \lor (Y \land X) \equiv Y$):

\[
\begin{align*}
\mu X &= Y \lor Z \\
\nu Y &= Z \\
\mu Z &= Y \land X
\end{align*}
\quad \rightarrow \quad
\begin{align*}
\mu X &= Y \\
\nu Y &= Y \land X \\
\mu Z &= Y \land X
\end{align*}
\quad \rightarrow \quad
\begin{align*}
\mu X &= Y \land X \\
\nu Y &= Y \land X \\
\mu Z &= Y \land X
\end{align*}
\]

Next, one obtains $X = \bot$ by a local elimination step in the first equation, using that $Y \land \bot \equiv \bot$. This solution can then be substituted forward by Theorem 6.10, to obtain the full solution $(\bot, \bot, \bot)$. In general, steps 1 and 2 must be mixed.

The next example shows a PBES where unfolding $X$ in its own definition makes sense.
Applying Theorem 4.3 to unfold \( \sigma X; \nu Y; S_2 \) with different sign. It occurs already in \cite{Mad97, Lemma 3.23}, but our proof is different.

Example 7.3. Applying Theorem 4.3 to unfold \( X \) in its own definition, we get:

\[
\begin{align*}
\mu X(b) &= (b \land Y) \lor X(\neg b) \\
\nu Y &= X(\top)
\end{align*}
\]

Applying Theorem 4.3 again, to unfold \( X \) in \( Y \) yields \( \nu Y = Y \lor X(\top) \), hence by local resolution \( Y = \top \), hence \( X(b) = \top \).

7.2. Reordering Variables. Theorem 5.1 indicates that two adjacent variables with the same sign may be interchanged. This theorem occurs already in \cite[Lemma 3.21]{Mad97}. For PBES it is repeated in \cite[Lemma 21]{GW05a}. However, \cite[GW05a]{Mad97} don’t give a full proof, but refer to Bekić Lemma. In our proof, we show exactly how Theorem 4.3 reduces to Bekić Lemma (Lemma 2.1.9). In other works \cite{Sei96, KNIU19}, adjacent variables with the same sign are grouped in unordered blocks. No claim is made about the correctness of such a definition.

Theorem 5.9 shows the inequality that arises when interchanging adjacent variables with different sign. It occurs already in \cite[Lemma 3.23]{Mad97}, but our proof is different. Our proof depends on a probably new inequality in fixpoint calculus, which we coin Bekić Inequality (Lemma 2.2.4).

Theorem 6.9 is a new result. It states that in the special case that \( X \) and \( Y \) are not on the same dependency loop, they can be interchanged without modifying the solution.
This generalizes [GW05a, Lemma 19], which requires that the right-hand side of \( Y \) in \( E \) is a constant, i.e., \( \text{indep}(E, Y, Z) \) for all \( Z \).

Finally, Theorem 5.7 in this form is new. It allows to swap whole blocks of equations. Mader [Mad97, Lemma 3.22] claims a similar result, under the condition that both \( \text{indep}(E, S_1, S_2) \) and \( \text{indep}(E, S_2, S_1) \). However, [GW05a] show a counter example to this. The repair in [GW05a, Lemma 22] requires that \( S_3 \) is empty. We show a stronger result: if \( S_3 \) is empty, only one of the requirements \( \text{indep}(S_2, S_1) \) or \( \text{indep}(S_2, S_1) \) is needed.

Notably, our result even applies to nonempty \( S_3 \), provided we have \( \text{indep}(S_1, S_2; S_3) \) (or its reverse), i.e. \( S_1 \) is also independent on the variables in \( S_3 \). Note that we allow arbitrary (dependent) alternations within \( S_1 \) and \( S_2 \), and even \( S_2 \) might depend on \( S_1 \). We lifted two other unnecessary restrictions: surprisingly, this result doesn't require monotonicity of \( E \). Also, the results in [Mad97, GW05a] are for individual equations only, while we can swap whole blocks at the same time.

We now show an application of swapping blocks to reduce the number of \( \mu/\nu \)-alternations.

**Example 7.4.** Consider the following four Boolean Equation Systems:

\[
\begin{array}{|c|c|c|c|}
\hline
B_3 & B_4 & B_5 & B_6 \\
\hline
\mu X = Y & \mu X = Y & \nu Z = W & \mu X = Y \\
\mu Y = X & \nu Z = W & \mu X = Y & \mu Y = X \\
\nu Z = W & \mu Y = X & \mu Y = X & \mu W = Z \\
\mu W = Z & \mu W = Z & \mu W = Z & \nu Z = W \\
\hline
\end{array}
\]

For these BES, the dependency graph between the variables consists of two loops, \( X \leftrightarrow Y \) and \( Z \leftrightarrow W \). In particular, we have \( \text{indep}\{\{X, Y\}, \{Z, W\}\} \). We want to transform \( B_3 \) to \( B_5 \), because it has fewer alternations. Theorem 5.1 cannot be applied, because the sign of \( Z \) is different from all the others.

Using Theorem 5.7 on individual equations, one can show that \([B_3] = [B_4]\), because \( \text{indep}(Y, \{Z, W\}) \). However, one cannot derive \([B_4] = [B_5]\) using Theorem 5.7, because neither \( \text{indep}(X, \{Z, Y, W\}) \), nor \( \text{indep}(\{Z, Y, W\}, X) \) holds. However, one can prove \( B_3 = B_5 \) directly with Theorem 5.7, by swapping block \( \{X, Y\} \) with \( Z \), because indeed we have \( \text{indep}(\{X, Y\}, \{Z, W\}) \). Alternatively, one can observe that \( X \not\# Z \), and apply Theorem 6.9 to deduce that \( B_4 = B_5 \) directly.

All theorems fail to prove the equivalence of \( B_{3-5} \) with \( B_6 \). However, Theorem 5.9 guarantees that \([B_6] \leq [B_3] \). As a matter of fact, the solution of \( B_3, B_4, B_5 \) is \((X = \perp, Y = \perp, Z = \top, W = \top)\), while the solution of \( B_6 \) is \((X = \perp, Y = \perp, Z = \perp, W = \perp)\). The reader may verify this by Gauss Elimination, cf. Example 7.2. This shows that the reordering theorems cannot easily be strengthened.

### 7.3. Swapping Signs

The inequality of Theorem 5.10 is well known and appears for instance in [Mad97, Lemma 3.24]. Theorem 6.7 is new. It shows that the sign of variable \( X \) is only relevant when \( X \) is the most relevant variable on a dependency loop.

**Example 7.5.** Now consider the next three BESs which only differ in their fixpoint signs:

\[
\begin{array}{|c|c|c|}
\hline
B_7 & B_8 & B_9 \\
\hline
\mu X = Y & \mu X = Y & \mu X = Y \\
\nu Y = X \lor Z & \nu Y = X \lor Z & \mu Y = X \lor Z \\
\mu Z = Z \land W & \nu Z = Z \land W & \mu Z = Z \land W \\
\nu W = X \land \perp & \nu W = X \land \perp & \mu W = X \land \perp \\
\hline
\end{array}
\]
Like before, want to manipulate $B_7$ to reduce the number of fixpoint alternations. We identify two possibilities. First, we may flip the sign of $Z$, obtaining $B_8$, which has the solution $(\top, \top, \bot, \bot)$. By Theorem 5.10, it holds that $[B_7] \leq [B_8]$ and so we conclude that also $[B_7](Z) = [B_7](W) = \bot$. The other option is to flip the sign of $Y$ and $W$, yielding $B_9$. Since $Y \not\leftarrow^+ Y$ in $Y, Z, W$, Theorem 6.7 gives that $[B_7] = [B_9]$.

7.4. Other Results. Along the way, we proved (and proof checked) several lemmas on FES that may be interesting on their own. For quick reference, we summarize these in Table 2. Here $\eta$ denotes an arbitrary valuation. All these lemmas occur in some form in the literature. Lemma 3.8 states that the semantics indeed returns a solution, and follows from [Mad97, Lemma 3.5]. Lemma 5.3 corresponds to [Mad97, Lemma 3.10] (which is not proved there) and [GW05a, Lemma 7]. Actually, [Mad97] has Lemma 5.6, which is equivalent according to our Theorem 5.7. Lemma 3.9 and 5.8 are from [Mad97, Lemma 3.14] as well, and Lemma 5.5 follows directly from Lemma 5.3. We included it here to stress that right congruence doesn’t hold in general.

Finally, we needed some basic results on fixpoints in complete lattices, cf. Lemma 2.1 and 2.2. The existence and definition of least and greatest fixpoints is due to Knaster (on sets) and Tarski (on complete lattices) [Tar55], see [LNS82] for a historical account. We (re)proved a number of identities (Lemma 2.1) and inequalities (Lemma 2.2) on fixpoint expressions. Most of these results are known. Lemma 2.1.1-6 can for instance be found in [Bac02]. Rule 9 (Bekić Equality) can be found in e.g. [dB80, Bek84], but stated in a different form, involving simultaneous fixpoints. We have not found in the literature the inequality in Lemma 2.2.4, which resembles Bekić equality on terms with mixed minimal and maximal fixpoints.

8. Formalisation in Coq & PVS

We have formalised all of the above theory in both Coq [Ber08, S+23] and PVS [OS08]. A replication artefact containing these proofs is available at [NvdP24]. The formalized definitions and proofs follow the definitions and proof steps in this paper quite closely. Here, we highlight the main difference between the two formalisations.
In Coq, we captured the concepts of complete lattices and monotonic functions in typeclasses. For these, we defined several typeclass instances, for example the product lattice and composition of monotonic functions. In many cases, Coq is able to perform automatic typeclass resolution, saving us from manually proving monotonicity of complex functions, for example those in Lemma 2. Furthermore, Coq supports user-defined notation, allowing us to closely follow the notation used in the paper. The proofs for showing decidability of $X \xrightarrow{E,S} Y$ are extensive, something that is not reflected in the paper.

Our PVS definitions and proofs were originally developed under PVS version 4.2, but could be ported to version 7.1 with minimal effort. Contrary to Coq, PVS is built on classical logic and thus allows the law of excluded middle (for all propositions $P$, it holds $P \lor \neg P$). We thus do not need to supply proofs for decidability of $X \xrightarrow{E,S} Y$. This also means that we do not rely on finiteness of $S$, and thus the definition of $\xrightarrow{}$ only depends on $E$ and the domain $E$ is restricted where necessary, e.g., in Theorem 6.7. This simplifies the proof of Lemma 6.2: it can operate on $\text{split}_{X,E}$ directly.

9. Conclusion

We provided several equalities and inequalities involving a range of operations on fixpoint equation systems (FES). We refer to Table 1 and 2 (Section 7) for a summary of the theorems. Lemmas 2.1 and 2.2 provide a useful overview on equalities and inequalities for nested fixed points in complete lattices.

We provided self-contained and detailed proofs of all results and mechanised these proofs in two proof assistants, Coq and PVS.

By the generic nature of FES, these results carry over to other formalisms such as Boolean equation systems (BES), parity games (and variations thereof), and parameterised (first-order) Boolean equation systems (PBES).

Acknowledgment

Large part of the research was carried out at the Centrum voor Wiskunde en Informatica.
