ABSTRACT. We study the relational graph models that constitute a natural subclass of relational models of λ-calculus. We prove that among the λ-theories induced by such models there exists a minimal one, and that the corresponding relational graph model is very natural and easy to construct. We then study relational graph models that are fully abstract, in the sense that they capture some observational equivalence between λ-terms. We focus on the two main observational equivalences in the λ-calculus, the λ-theory $H^+$ generated by taking as observables the β-normal forms, and $H^*$ generated by considering as observables the head normal forms. On the one hand we introduce a notion of λ-König model and prove that a relational graph model is fully abstract for $H^+$ if and only if it is extensional and λ-König. On the other hand we show that the dual notion of hyperimmune model, together with extensionality, captures the full abstraction for $H^*$.

INTRODUCTION

The untyped λ-calculus is a paradigmatic programming language introduced by Church in [25]. It has a prominent role in theoretical computer science [7] and, despite its very simple syntax, it is Turing-complete [53, 87]. Its denotational models have been fruitfully used for proving the consistency of extensions of β-convertibility, called λ-theories, and for exposing operational features of λ-terms. The first model of λ-calculus, $D_\infty$, was defined by Scott in the pioneering article [81]. Subsequently, a wealth of models have been introduced in various categories of domains and classified into semantics according to the nature of their representable functions. Scott’s continuous semantics [82] corresponds to the category whose objects are complete partial orders and morphisms are continuous functions. The stable semantics [12] and the strongly stable semantics [19] are refinements of the continuous semantics, introduced to capture the notion of “sequential” continuous function. In each of these semantics all the models come equipped with a partial order, and some of them, called webbed models, are built from lower level structures called “webs” [10]. The simplest class of webbed models is the class of graph models [62], which was isolated in the seventies by Plotkin, Scott and Engeler within the continuous semantics [39, 73, 82].

In each of the aforementioned semantics there exists a continuum of models inducing pairwise distinct λ-theories. Nevertheless, certain models are particularly important because they allow to capture operational properties of the λ-terms. For instance, two λ-terms have the same interpretation in Engeler’s graph model $\mathcal{E}$ exactly when they are equal in the
\(\lambda\)-theory \(\mathcal{B}\), which equates all \(\lambda\)-terms having the same Böhm tree. The main technical tool for proving such a result is the Approximation Theorem \([45]\), stating that the interpretation of a \(\lambda\)-term is given by the supremum of the interpretations of the finite approximants of its Böhm tree. Other models are significant because they are fully abstract, which means that the induced \(\lambda\)-theory captures some observational equivalence between \(\lambda\)-terms. A celebrated result by Hyland \([47]\) and Wadsworth \([89]\) shows that Scott’s \(D_\infty\) is fully abstract for the \(\lambda\)-theory \(\mathcal{H}^*\), that corresponds to the observational equivalence where the observables are the head normal forms. In \([26]\), Coppo, Dezani-Ciancaglini and Zacchi constructed a filter model \(D_{\text{cdz}}\) and proved that it is fully abstract for \(\mathcal{H}^+\), the observational equivalence where the observables are the \(\beta\)-normal forms. The \(\lambda\)-theory \(\mathcal{H}^+\) is the original extensional observational theory defined by Morris in his thesis \([69]\). It is maybe less ubiquitously studied in the literature than \(\mathcal{H}^*\) but we believe is equally important. For instance, its notion of observables is central in the Böhm Theorem \([14]\) and in other separability results \([28]\).

**Graph Models in the Relational Semantics.** In the present paper we focus on the relational semantics of \(\lambda\)-calculus, that has been introduced by Girard as a quantitative model of linear logic in \([43]\). The first concrete examples of relational models of \(\lambda\)-calculus were built in \([20, 49]\). Recently, Manzonetto and Ruoppolo individuated the subclass of relational graph models encompassing all previous examples \([67]\). The definition of a relational graph model (Definition 3.4) really is the relational analogue of the definition of a graph model living in the continuous semantics. In particular, relational graph models can be built by free completion and by forcing like the continuous ones. However, from the point of view of the induced \(\lambda\)-theories, they share more similarities with filter models. For instance, the relational graph model \(D_\omega\) built in \([20]\) has the same theory as Scott’s \(D_\infty\), namely it is fully abstract for \(\mathcal{H}^*\) \([65]\). Similarly, the model \(D_\star\) from \([67]\) is fully abstract for \(\mathcal{H}^+\), like the filter model \(D_{\text{cdz}}\). On the other hand, no graph model living in the continuous semantics can represent such \(\lambda\)-theories because no graph model is extensional. When comparing relational graph models with filter models inducing the same \(\lambda\)-theory, one can see that the former are in general simpler because their elements are not partially ordered. Moreover, an element \(\sigma\) in the relational interpretation of a \(\lambda\)-term \(M\) carries information concerning intensional properties of \(M\). In particular, from \(\sigma\) it is possible to compute a bound to the number of head-reduction steps towards its normal form and infer the amount of resources consumed by \(M\) during such a reduction sequence \([30, 31]\).

**Relational Graph Models as Type Systems.** The Stone duality between filter models and intersection type systems has been widely studied in the literature, e.g., \([2, 27, 45, 9, 80]\). (We refer to Ronchi Della Rocca and Paolini’s book for a thoughtful discussion \([77, \text{Ch. 13}\]).) Such a correspondence shows that some interesting classes of domain-based models can be described in logical form. The intuition is that a functional intersection type \(\alpha_1 \land \cdots \land \alpha_n \rightarrow \beta\) can be seen as a continuous step function sending the set \(\{\alpha_1, \ldots, \alpha_n\}\) to the element \(\beta\). Types come equipped with inference rules reflecting the structure of the underlying domain. In \([72]\), Paolini et al. introduce the strongly linear relational models (a class encompassing relational graph models, but included in the linear relational models of \([66]\)) and show that they can be represented as relevant (i.e., without weakening) intersection type systems where the intersection is a non-idempotent operation (it is actually a linear logic tensor \(\otimes\)). The idea, already present in \([30]\), is that in the absence of idempotency and partial orders the
type $\alpha_1 \land \cdots \land \alpha_n \rightarrow \beta$ can be seen as a relation associating the multiset $[\alpha_1, \ldots, \alpha_n]$ with the element $\beta$. As a consequence of the work in [72], all relational graph models can be presented in logical form, that is, as non-idempotent intersection type systems. We use this kind of representation to expose and exploit their quantitative features.

The Approximation Theorem. Besides soundness (Theorem 3.15), one of the main properties enjoyed by relational graph models is the Approximation Theorem (Theorem 4.16). Typically such a theorem is proved by exploiting Wadsworth’s stratified refinements of the $\beta$-reduction [89], that also work in the relational framework as shown in [65]. Other techniques are based on Tait and Girard’s reducibility candidates [85, 42], that are widespread in logic and the theory of programming languages [75, 56, 57, 9], but notoriously give rise to proofs based on impredicative principles. Thanks to its quantitative nature, in the context of the relational semantics it is possible to get rid of the traditional methods and provide a combinatorial proof. This is the case of the proof given in [67] by relying on these facts:

- Relational graph models are also models of Ehrhard’s differential $\lambda$-calculus [37] and Tranquilli’s resource calculus [86]. This follows from the fact that they all are linear reflexive objects in the Cartesian closed differential category $\mathbf{MRel}$ [66].
- An easy induction shows that the interpretation of a $\lambda$-term $M$ in a relational graph model is equal to the interpretation of its Taylor expansion [37], which is a representation of $M$ as a power series of resource approximants (replacing in a way the finite approximants of its Böhm tree).
- The usual Approximation Theorem follows from the above result by applying a theorem due to Ehrhard and Regnier [38] stating that the normal form of the Taylor expansion of $M$ coincides with the Taylor expansion of its Böhm tree.

In Section 4.5 we provide a new combinatorial proof of the Approximation Theorem by exploiting the logical presentation discussed above. We are going to associate a measure with the derivation tree $\pi$ of $\Gamma \vdash M : \alpha$ and show that when $M \beta$-reduces to $N$ by contracting a redex $R$ two cases are possible: either there exists a derivation of $\Gamma \vdash N : \alpha$ having a strictly smaller measure, or $\pi$ is a derivation of $\Gamma \vdash M\{\bot/\downarrow\} : \alpha$, where $M\{\bot/\downarrow\}$ denotes the approximant obtained by substituting a constant $\bot$ for the redex $R$ in $M$. In both cases, either the measure of the derivation or the number of redexes in $M$ has decreased. Therefore the Approximation Theorem follows by a simple induction over the ordinal $\omega^2$.

The Minimal Relational Graph Theory. Every relational graph model induces a $\lambda$-theory through the kernel of its interpretation function. We call relational graph theories those $\lambda$-theories induced by some relational graph models. A natural question that arises is what $\lambda$-theories are in addition relational graph theories. We do not provide a characterization, but we show that the $\lambda$-theories $\mathcal{B}$, $\mathcal{H}^+$ and $\mathcal{H}^*$ are. Another question is whether there exists a minimal relational graph theory: for instance, in [22] Bucciarelli and Salibra proved that the minimal $\lambda$-theory among the ones represented by usual graph models exists, but their construction of the minimal model is complicated and what $\lambda$-terms are actually equated in the minimal theory remains a mystery. In Section 5 we show not only that a minimal relational graph theory exists, but also that such a $\lambda$-theory is actually $\mathcal{B}$. Also, the corresponding model $\mathcal{E}$ is very simple to define (its construction is actually analogous to the one of Engeler’s graph model). Moreover, we prove that even the preorder induced by $\mathcal{E}$
on λ-terms is minimal among representable inequational theories. Our model \( E \) shares many properties with Ronchi Della Rocca’s filter model defined in [76].

**Characterizing Fully Abstract Models.** In the literature there are many full abstraction theorems, namely results showing that some observational equivalence arises as the theory of a suitable denotational model. However, until recently, researchers were only able to prove full abstraction results for individual models [47, 89, 26], or at best to provide sufficient conditions for models living in some class to be fully abstract [65, 67, 44]. For instance, Manzonetto showed in [65] that a model of λ-calculus living in a cpo-enriched Cartesian closed category is fully abstract for \( \mathcal{H}^* \) whenever it is a “well stratified \( \bot \)-model”\(^1\). More recently, he proved in collaboration with Ruoppolo that every extensional relational graph model preserving the polarities of the empty multiset (in a technical sense) is fully abstract for \( \mathcal{H}^+ \) [67]. A substantial advance in the study of full abstraction was made in [16], where Breuvart proposed a notion of *hyperimmune* model of λ-calculus, and showed that a \( K \)-model\(^2\) living in the continuous semantics is fully abstract for \( \mathcal{H}^* \) if and only if it is extensional and hyperimmune, thus providing a characterization. In Section 6 we define the dual notion of λ-\( \text{König} \) model and prove that a relational graph model is fully abstract for \( \mathcal{H}^+ \) exactly when it is extensional and λ-\( \text{König} \). In Section 7 we show that the notion of hyperimmune continuous model has a natural counterpart in the relational semantics and that, also in the latter case, together with extensionality gives a characterization of all relational graph models fully abstract for \( \mathcal{H}^* \).

**Related Works.** The primary goal of this article is to provide a uniform and self-contained treatment of relational graph models and their properties. In particular, we present some semantical results recently appeared in the conference papers [67, 18]. (The syntactic results in [18] will be the subject of a different paper [50] in connection with the \( \omega \)-rule.) Besides giving more detailed proofs and examples, we provide several original results, like a quantitative proof of the Approximation Theorem, the characterization of the minimal representable theory, and the characterization of all relational graph models that are fully abstract for \( \mathcal{H}^* \). A natural comparison is with the article [72], where Paolini et al. introduce the notion of strongly linear relational model and show that such models correspond to their notion of *essential* type systems. We remark that their work rather focuses on the properties enjoyed by those systems, like (weighted) subject reduction/expansion and adequacy, while we focus on the representable λ-theories and provide general full abstraction results.

The relational semantics, being very versatile, can also be used to model the call-by-value and the call-by-push-value λ-calculus [61], as well as non-deterministic [32, 33, 4] and resource sensitive extensions [37, 38] of λ-calculus. We refer the reader to [35, 24] for a relational semantics of the call-by-value λ-calculus and to [36] for the call-by-push-value. For non-deterministic calculi, see [21] in the call-by-name setting and [34] in the call-by-value one. Relational models of differential and resource calculi have been studied in [70, 66, 15]. The relational semantics has been generalized by considering multisets with infinite multiplicities to build models that are not sensible [23], and by replacing relations with matrices of scalars to provide quantitative models of non-deterministic PCF [58]. An even more abstract

---

\(^1\)Using the terminology of [65].

\(^2\)The class of \( K \)-models, which contains all graph models, was isolated by Krivine in [56].
perspective, where the categorical notion of profunctors takes the role of relations, was contemplated in [40, 48].

**Outline.** In Section 1 we present some notions and notations, mainly concerning $\lambda$-calculus, that are useful in the rest of the article. In Section 2 we review some literature concerning the observational equivalences corresponding to $H_+$ and $H^*$, and their characterizations in terms of extensional equivalences on Böhm trees. In Section 3 we define the class of relational graph models, show how to build them via free completion of a partial pair, and prove the soundness. In Section 4 we provide the presentation of relational graph models in logical form, exhibit their quantitative features and prove the Approximation Theorem. Section 5 is devoted to present the Engeler-style relational graph model and prove that the induced (inequational) theory is minimal. In Section 6 and Section 7 we provide the characterizations of all relational graph models that are fully abstract for $H_+$ and $H^*$.

1. Preliminaries

1.1. Coinduction. In this article we will often use coinductive structures and coinductive reasoning. We recall here some basic facts about coinduction and discuss some terminology, but we mainly take them for granted. Nice tutorials on the subject are [52, 55]; see also [1].

A coinductive structure, corresponding to a coinductive datatype, is just the greatest fixed point over a grammar, or equivalently the terminal coalgebra over the corresponding functor. We also consider coinductive propositions (and relations), that are the greatest propositions over such coinductive structures respecting the structural constraints. Coinductive propositions are proven by infinite derivation trees that are coinductive structures.

As opposed to the inductive principle, the coinductive one is unable to destruct a coinductive object, it is only able to construct one. More precisely, we can prove by coinduction a statement of the form $\forall x \in X \exists y \in Y \varphi(x, y)$ where $Y$ and $\varphi$ are coinductively defined. Consider for now the simpler case where we want to prove $\forall x \in X \varphi(x)$ for some coinductive proposition $\varphi$. In order to apply the coinduction principle, it is sufficient to show

$$\forall x \in X \exists n \in \mathbb{N} \exists \vec{x} \in X^n \left( \bigwedge_{i \leq n} \varphi(x_i) \Rightarrow \varphi(x) \right)$$

where the “$p$” in $\Rightarrow$ refers to the productivity of the implication. In this case “productive” means that in the proof of the implication some patterns of the grammar coinductively defining $\varphi$ are actually applied to the various $\varphi(x_i)$. Usually $x$ is a certain (inductive or coinductive) structure and $\vec{x}$ can be seen as an “unfolding” of $x$.

In the general case, namely $\forall x \in X \exists y \in Y \varphi(x, y)$, it is sufficient to show that

$$\forall x \in X \exists n \in \mathbb{N} \exists \vec{x} \in X^n \forall \vec{y} \in Y^n \exists p y \in Y \left( \bigwedge_{i \leq n} \varphi(x_i, y_i) \Rightarrow \varphi(x, y) \right).$$

The “productivity” of the existential $\exists p$ simply requires that $y = p(y_1, \ldots, y_n)$ for some pattern $p$ of the grammar coinductively generating $Y$. Notice that the negation of a coinductive statement is inductive and *vice versa*, a fact that we use in the proof of Lemma 5.5.

Since structural coinduction has been around for decades and many efforts have been made in the community to explain why it should be used as innocently as structural induction, in our proofs we will not reassert the coinduction principle every time it is used. Borrowing
the terminology from [55], we say that we apply the “coinductive hypothesis” whenever the
coinduction principle is applied. We believe that this mathematical writing greatly improves
the readability of our proofs without compromising their correctness: the suspicious reader
can study [55] where it is explained how this informal terminology actually corresponds to a
formal application of the coinduction principle.

1.2. Sets, Functions and Multisets. We denote by \( \mathbb{N} \) the set of natural numbers and by
\( \mathbb{N}^+ \) the set of strictly positive natural numbers.

Let \( A, B \) be two sets. We write \( \mathcal{P}(A) \) for the powerset of \( A \), and \( \mathcal{P}_f(A) \) for the set of all
finite subsets of \( A \). Given a function \( f : A \rightarrow B \) we write \( \text{dom}(f) \) for its domain.

A multiset over \( A \) is a partial function \( a : A \rightarrow \mathbb{N}^+ \). Given \( a \in A \) and a multiset \( a \) over
\( A \), the multiplicity of \( a \) in \( a \) is given by \( a(\alpha) \). A multiset \( a \) is called finite if \( \text{dom}(a) \), which
is called its support, is finite. A finite multiset \( a \) will be represented as an unordered list of
its elements \( [a_1, \ldots, a_n] \), possibly with repetitions. The empty multiset is denoted by \( \omega \). We
write \( \mathcal{M}_f(A) \) for the set of all finite multisets over \( A \). Given \( a_1, a_2 \in \mathcal{M}_f(A) \), their multiset
union is denoted by \( a_1 + a_2 \) and defined as a pointwise sum.

1.3. Sequences and Trees. We denote by \( \mathbb{N}^{<\omega} \) the set of all finite sequences over \( \mathbb{N} \). An
arbitrary sequence is of the form \( \sigma = \langle n_1, \ldots, n_k \rangle \). The empty sequence is denoted by \( \epsilon \).

Let \( \sigma = \langle n_1, \ldots, n_k \rangle \) and \( \tau = \langle m_1, \ldots, m_{k'} \rangle \) be two sequences and let \( n \in \mathbb{N} \). We write:
- \( \sigma.n \) for the sequence \( \langle n_1, \ldots, n_k, n \rangle \),
- \( \sigma \cdot \tau \) for the concatenation of \( \sigma \) and \( \tau \), that is for the sequence \( \langle n_1, \ldots, n_k, m_1, \ldots, m_{k'} \rangle \).

Given a function \( f : \mathbb{N} \rightarrow \mathbb{N} \), its prefix of length \( n \) is the sequence \( \langle f|n \rangle = \langle f(0), \ldots, f(n - 1) \rangle \).

**Definition 1.1** (Trees and subtrees).
- A tree is a partial function \( T : \mathbb{N}^{<\omega} \rightarrow \mathbb{N} \) such that \( \text{dom}(T) \) is closed under prefixes and
for all \( \sigma \in \text{dom}(T) \) and \( n \in \mathbb{N} \) we have \( \sigma.n \in \text{dom}(T) \) if and only if \( n < T(\sigma) \).
- We write \( T \) for the set of all trees.
- The subtree of \( T \) at \( \sigma \) is the tree \( T|_{\sigma} \) defined by \( T|_{\sigma}(\tau) = T(\sigma \cdot \tau) \) for all \( \tau \in \mathbb{N}^{<\omega} \).

The elements of \( \text{dom}(T) \) are called positions. For all \( \sigma \in \text{dom}(T) \), \( T(\sigma) \) gives the number
of children of the node in position \( \sigma \). Hence \( T(\sigma) = 0 \) when \( \sigma \) corresponds to a leaf.

**Definition 1.2.** A tree \( T \) is called:
- recursive if the function \( T \) is partial recursive (after coding);
- finite if \( \text{dom}(T) \) is finite;
- infinite if it is not finite.

We denote by \( T^{\infty} \) (resp. \( T^{\infty}_{\text{rec}} \)) the set of all infinite (resp. recursive infinite) trees.

**Definition 1.3** (Infinite paths). A function \( f : \mathbb{N} \rightarrow \mathbb{N} \) is an infinite path of \( T \) if \( \langle f|n \rangle \in \text{dom}(T) \) for all \( n \in \mathbb{N} \). We denote by \( \Pi(T) \) the set of all infinite paths of \( T \).

By König’s lemma, a tree \( T \) is infinite if and only if \( \Pi(T) \neq \emptyset \).
1.4. Category Theory. Concerning category theory we mainly use the notations from [5].

Let \( C \) be a category and \( A, B, C \) be arbitrary objects of \( C \). We write \( C(A, B) \) for the homset of morphisms from \( A \) to \( B \). When there is no chance of confusion we simply write \( f : A \to B \) instead of \( f \in C(A, B) \). Given two morphisms \( f : A \to B \) and \( g : B \to C \), their composition is indicated by \( g \circ f : A \to C \).

When the category \( C \) is Cartesian, we denote by \( \top \) the terminal object, by \( A \times B \) the categorical product of \( A \) and \( B \), by \( \pi_1 : A \times B \to A \), \( \pi_2 : A \times B \to B \) the associated projections and, given a pair of arrows \( f : C \to A \) and \( g : C \to B \), by \( \langle f, g \rangle : C \to A \times B \) the unique arrow such that \( \pi_1 \circ \langle f, g \rangle = f \) and \( \pi_2 \circ \langle f, g \rangle = g \). We write \( f \times g \) for the product map of \( f \) and \( g \) which is defined by \( f \times g = \langle f \circ \pi_1, g \circ \pi_2 \rangle \).

When \( C \) is in addition Cartesian closed we write \( A \Rightarrow B \) for the exponential object and \( \text{ev}_{AB} : (A \Rightarrow B) \times A \to B \) for the evaluation morphism. Moreover, for any object \( A \) and morphism \( f : A \to B \), whenever \( f \neq g \), there exists a morphism \( h : \top \to A \) such that \( f \circ h \neq g \circ h \). Similarly, an object \( A \) is well-pointed if the property above holds for all \( f, g : A \to A \).

We say that \( D = (D, \text{App}, \lambda) \) is a reflexive object (living in \( C \)) if \( D \) is an object of \( C \) and \( \text{App} : D \to (D \Rightarrow D), \lambda : (D \Rightarrow D) \to D \) are morphisms such that \( \text{App} \circ \lambda = \text{Id}_{D \Rightarrow D} \). A reflexive object \( D \) is called extensional whenever \( \lambda \circ \text{App} = \text{Id}_D \).

1.5. The Lambda Calculus. We generally use the notation of Barendregt’s book [7] for \( \lambda \)-calculus. The set \( \Lambda \) of \( \lambda \)-terms over a denumerable set \( \text{Var} \) of variables is defined by:

\[
\Lambda : \quad M, N, P, Q ::= x \mid \lambda x.M \mid MN \quad \text{for all } x \in \text{Var}.
\]

We assume that the application associates to the left and has a higher precedence than \( \lambda \)-abstraction. For instance, we write \( \lambda x y z . x y z \) for the \( \lambda \)-term \( \lambda x . (\lambda y . (\lambda z . (x y) z)) \). Moreover, we often write \( \bar{x} \) for the sequence \( (x_1, \ldots, x_n) \) and \( \lambda \bar{x}.M \) for \( \lambda x_1 \ldots \lambda x_n.M \).

The set \( \text{FV}(M) \) of free variables of \( M \) and the \( \alpha \)-conversion are defined as in [7, Ch. 1 §2]. Hereafter, we consider \( \lambda \)-terms up to \( \alpha \)-conversion.

Definition 1.4. A \( \lambda \)-term \( M \) is closed whenever \( \text{FV}(M) = \emptyset \) and in this case it is also called a combinator. The set of all combinators is denoted by \( \Lambda^0 \).

We often consider relations on \( \lambda \)-terms that have the property of being “context closed”. Intuitively a context \( C[-] \) is a \( \lambda \)-term with a hole denoted by \( [-] \). Formally, the hole is an algebraic variable and contexts are defined as follows.

Definition 1.5.

• A context \( C[-] \) is generated by the grammar (for \( x \in \text{Var} \)):

\[
C[-] ::= [-] \mid x \mid \lambda x.C[-] \mid (C_1[-])(C_2[-])
\]

• A context \( C’[-] \) is called single hole if it has a unique occurrence of the algebraic variable \([-] \). Single hole contexts are generated by (for \( M \in \Lambda \)):

\[
C’[-] ::= [-] \mid \lambda x.C’[-] \mid M(C’[-]) \mid (C’[-])M
\]

• A context \( H[-] \) is a head context if it has the shape \( (\lambda x_1 \ldots x_n.[-])M_1 \cdots M_k \) for some \( n, k \geq 0 \) and \( M_1, \ldots, M_k \in \Lambda \).
Given a context $C[\cdot]$, we write $C[M]$ for the $\lambda$-term obtained from $C[\cdot]$ by substituting $M$ for the hole $[\cdot]$, possibly with capture of free variables in $M$.

A relation $R \subseteq \Lambda \times \Lambda$ is context closed whenever $M \mathrel{R} N$ entails $C[M] \mathrel{R} C[N]$ for all single hole contexts $C[\cdot]$. The context closure of a relation $R \subseteq \Lambda \times \Lambda$ is the smallest context closed relation $R'$ containing $R$.

Reductions. The $\lambda$-calculus is a higher-order term rewriting system and several notions of reduction can be considered. As a matter of notation, given a reduction $R$, we write $\rightarrow_R$ for its context closure, $\rightarrow_{\textrm{reflex}}$ for the transitive and reflexive closure of $\rightarrow_R$, finally $\Rightarrow_R$ for the corresponding $R$-conversion, that is the transitive, reflexive and symmetric closure of $\rightarrow_R$. We denote by $\text{nf}_R(M)$ the $R$-normal form ($R$-nf, for short) of $M$ (if it exists) and by $\text{NF}_R$ the set of all $R$-normal forms. Given two reductions $R_1, R_2$ we denote their union by simple juxtaposition, i.e., $\rightarrow_{R_1 \cup R_2}$.

The main notion of reduction is the $\beta$-reduction, which is the context closure of:

$$\lambda x. M \rightarrow M\{N/x\} \quad \text{(}\beta\text{)}$$

where $M\{N/x\}$ denotes the capture-free simultaneous substitution of $N$ for all free occurrences of $x$ in $M$. The term on the left hand-side of the arrow is called $\beta$-redex, while the term on the right hand-side is its $\beta$-contractum.

A $\lambda$-term $M$ is in $\beta$-normal form if and only if $M = \lambda \vec{x}. M_1 \cdots M_k$ and each $M_i$ is in $\beta$-normal form. We say that $M$ has a $\beta$-normal form whenever $\text{nf}_\beta(M)$ exists.

It is well known that the $\lambda$-calculus is an intensional language — there are $\beta$-different $\lambda$-terms that are extensionally equal. This justifies the definition of the $\eta$-reduction:

$$\lambda x. M x \rightarrow M \text{ provided } x \notin \text{FV}(M). \quad \text{(}\eta\text{)}$$

Notice however that, when $M$ is a $\lambda$-abstraction, the $\eta$-reduction is actually a $\beta$-step.

Useful combinators and encodings. Concerning specific combinators, we fix the following notations:

- $I = 1_0 = \lambda x. x$
- $K = \lambda x y. x$
- $I_{n+1} = \lambda x y. x(I_n y)$
- $F = \lambda x y. y$
- $\Delta = \lambda x x$
- $c_n = \lambda f z. f^n(z)$
- $Y = \lambda f. (\lambda x. f(xx))(\lambda x. f(xx))$
- $\Omega = \Delta \Delta$
- $\text{J} = Y(\lambda j x j y)$

where $f^n(z) = f(\cdots f(f(z))) \cdots$, $n$ times. We will simply denote by $I$ the combinator $1_1 = \beta \lambda x. x$. It is easy to check that $I$ is the identity, $1_n$ is a $\beta\eta$-expansion of the identity, $K$ and $F$ are respectively the first and second projection, $\Omega$ is the paradigmatic looping combinator, $Y$ is Curry’s fixed point combinator, $c_n$ is the $n$-th Church’s numeral and $J$ is Wadsworth’s “infinite $\eta$-expansion of the identity” (see Section 2).

Given two $\lambda$-terms $M$ and $N$ their composition is defined by $M \circ N = \lambda x. M(Nx)$ and their pairing by $[M, N] = \lambda x. x MN$ (for $x \notin \text{FV}(MN)$). Moreover, it is possible to $\lambda$-define a given enumeration $(\lambda n)_{n \in \mathbb{N}}$ of closed $\lambda$-terms whenever such an enumeration is effective.

Definition 1.6. An enumeration of closed $\lambda$-terms $(\lambda n)_{n \in \mathbb{N}}$ is called effective (or uniform in [7, §8.2]) if there is a combinator $F \in \Lambda^o$ such that $F \lambda n = \beta \lambda n$ for all $n \in \mathbb{N}$.

As shown in [7, Def. 8.2.3], when the enumeration is effective, the sequence $[M]_{n \in \mathbb{N}}$ can be expressed (using the fixed point combinator $Y$) as a single $\lambda$-term satisfying:

$$[M_n]_{n \in \mathbb{N}} = \beta [M_0, [M_{n+1}]_{n \in \mathbb{N}}] = \beta [M_0, [M_1, [M_{n+2}]_{n \in \mathbb{N}}]] = \beta \cdots$$

Such infinite sequences will be mainly used in the following sections to build examples.
Solvability. Lambda terms are classified into solvable and unsolvable, depending on their capability of interaction with the environment, represented here by a context.

Definition 1.7.

- A λ-term M is solvable if there exists a head context H[−] such that $H[M] = \beta I$. Otherwise M is called unsolvable.
- Two λ-terms M, N are called separable if there exists a context C[−] such that $C[M] = \beta x$ and $C[N] = \beta y$ for some variables $x \neq y$.
- Two λ-terms M, N are called semi-separable if there exists a context C[−] such that C[M] is solvable while C[N] is unsolvable or vice versa.

Solvability has been characterized by Wadsworth in terms of head normalization in [88].

We recall that a λ-term M is in head normal form (hnf, for short) if it is of the form $M = \lambda x_1 \ldots x_n.x_iM_1 \cdots M_k$ for $n,k \geq 0$. Remark that in our notation the head variable $x_i$ can be either bound or free. A λ-term M has a hnf if it is β-converible to a hnf. The principal hnf of a λ-term M, denoted phnf(M), is the hnf obtained from M by head reduction $\rightarrow_h$, that is by repeatedly contracting the head redex $\lambda \vec{y}.(\lambda x.M)\vec{P}$ in M. We refer to [7, Def. 8.3.10] for a formal definition.

Theorem 1.8 (Wadsworth [88]).

A λ-term M is solvable if and only if M has a head normal form.

We say that M, N have similar hnf’s if phnf(M) = $\lambda x_1 \cdots x_n.x_iM_1 \cdots M_k$ and phnf(N) = $\lambda x_1 \cdots x_n'.x_iN_1 \cdots N_k'$ with $k - n = k' - n'$ and either $x_i$ is free or $i \leq \min\{n,n'\}$.

1.6. Böhm Trees. The Böhm trees, introduced by Barendregt in 1977 [6] and named after Corrado Böhm, are possibly infinite labelled trees representing the execution of a λ-term. The following coinductive definition is taken from [59] (see also [52]).

Definition 1.9. The Böhm tree BT(M) of a λ-term M is defined coinductively as follows:

- if M is unsolvable then BT(M) = ⊥;
- if M is solvable and phnf(M) = $\lambda x_1 \ldots x_n.x_iM_1 \cdots M_k$ then:

$$
\begin{align*}
\text{BT}(M) = & \lambda x_1 \ldots x_n.x_i \\
\text{BT}(M_1) \cdots \text{BT}(M_k)
\end{align*}
$$

Figure 1: Some examples of Böhm trees.
In Figure 1 we provide some notable examples of Bohm trees. Notice that in general $FV(BT(M)) \subseteq FV(M)$ but the converse might not hold. Indeed, given a $\lambda$-term $M$ satisfying $M \rightarrow_\beta \lambda z x. x(Mz)$, we have that $z \notin FV(BT(Mz))$ because $z$ is “pushed to infinity”.

We also present, as an auxiliary notion, the “Bohm-like trees”, which are labelled trees that look like Bohm trees but may not arise as a Bohm tree of a $\lambda$-term.

**Definition 1.10.** A Bohm-like tree is a labelled tree over $L = \{\bot\} \cup \{\lambda x. y \mid x, y \in \text{Var}\}$, that is a function $U : N^\omega \rightarrow L \times N$ such that $\pi_2 \circ U$ is a tree and $(\pi_1 \circ U)(\sigma) = \bot$ entails $(\pi_2 \circ U)(\sigma) = 0$. The tree $\pi_2 \circ U$ is called the underlying tree of $U$ and is denoted by $[U]$.

A Bohm-like tree $U$ is $\lambda$-definable if $U = BT(M)$ for some $M \in \Lambda$. In [7, Thm. 10.1.23], Barendregt gives the following characterization of $\lambda$-definable Bohm-like trees.

**Theorem 1.11.** Given a Bohm-like tree $U$, there exists a $\lambda$-term $M$ such that $BT(M) = U$ if and only if the restriction $U|_{\text{dom}_\bot(U)}$ where $\text{dom}_\bot(U) = \{\sigma \in \text{dom}(U) \mid (\pi_1 \circ U)(\sigma) \neq \bot\}$ is computable (after coding) and $FV(U)$ is finite.

The Bohm-like tree $\bot$ represents the absolute lack of information, therefore it makes sense to say that $\bot$ is “less defined” than any Bohm-like tree $U$. This is the consideration behind the order $\leq_\bot$ on Bohm-like trees defined below.

**Definition 1.12.** Given two Bohm-like trees $U, V$ we say that $U$ is an approximant of $V$, written $U \leq_\bot V$, whenever $U$ results from $V$ by replacing some subtrees by $\bot$.

**Approximations of Bohm trees.** A Bohm tree can be also seen as the least upper bound of its finite approximants, and finite approximants can be seen as the normal forms of a $\lambda$-calculus extended with a constant $\bot$ and an additional reduction $\rightarrow_\bot$.

A $\lambda_\bot$-term $M$ is a $\lambda$-term possibly containing occurrences of the constant $\bot$. The set $\Lambda_\bot$ of all $\lambda_\bot$-terms is generated by the grammar:

$\Lambda_\bot : M, N ::= \ x \mid \lambda x. M \mid MN \mid \bot$

Similarly a (single hole) $\lambda_\bot$-context is a (single hole) context $C[\ ]$ possibly containing occurrences of $\bot$. The $\bot$-reduction $\rightarrow_\bot$ is defined as the $\lambda_\bot$-contextual closure of the rules:

$$
\begin{align*}
\lambda_\bot : M. N & \rightarrow \bot \\
\bot M & \rightarrow \bot
\end{align*}
$$

The $\beta$- and $\eta$-reductions are extended to $\lambda_\bot$-terms in the obvious way. We write $\text{NF}_{\beta_\bot}$ for the set of $\lambda_\bot$-terms in $\beta_\bot$-normal forms and we denote its elements by $s, t, u, \ldots$.

The following characterization of $\beta_\bot$-normal forms is well known.

**Lemma 1.13.** Let $M \in \Lambda_\bot$. We have $M \in \text{NF}_{\beta_\bot}$ if and only if either $M = \bot$ or $M$ has shape $\lambda x_1 \ldots x_n. x_1 M_1 \cdots M_k$ (for some $n, k \geq 0$) and each $M_i$ is $\beta_\bot$-normal.

**Definition 1.14.** The size of $t \in \text{NF}_{\beta_\bot}$, written $\#t$, is defined by induction:

$$
\#\bot = 0, \quad \#(\lambda x. t) = 1 + \#t, \quad \#(x t_1 \cdots t_k) = 1 + \sum_{i=1}^k \#t_i.
$$

The preorder $\leq_\bot$ is defined on $\lambda_\bot$-terms as the $\lambda_\bot$-contextual closure of $\bot \leq M$. It is easy to check that, for all $t \in \text{NF}_{\beta_\bot}$, this definition and Definition 1.12 coincide.

The set of all finite approximants of the Bohm tree of $M$ can be obtained by calculating the direct approximants of all $\lambda$-terms $\beta$-convertible with $M$.

**Definition 1.15.** Let $M \in \Lambda_\bot$.

(1) The direct approximant of $M$, written $\text{da}(M)$, is the $\lambda_\bot$-term defined as:
Proof. Assume that

\[ \text{Lemma 1.16.} \]

Let \( \lambda \) be a non-empty subset of \( \Lambda \) and let \( C[\_\_] \) be a \( \lambda_\bot \)-context. If \( M = C[(\lambda x.P)Q] \) then \( \text{BT}^*(C[\bot]) \subseteq \text{BT}^*(M) \).

**Proof.** Assume that \( t \in \text{BT}^*(C[\bot]) \). By definition, there exists \( C'[\_] \) such that \( C[y] =_\beta C'[y] \), for some fresh variable \( y \), and \( t = \text{da}(C'[\bot]) \). Then \( C[(\lambda x.P)Q] =_\beta C'[(\lambda x.P)Q] \) and \( t = \text{da}(C'[(\lambda x.P)Q]) \), which implies that \( t \in \text{BT}^*(M) \). \qed

1.7. Inequational and Lambda Theories. Inequational theories and \( \lambda \)-theories become the main object of study when considering the computational equivalence more important than the process of computation.

**Definition 1.17.** An inequational theory is any context closed preorder on \( \Lambda \) containing the \( \beta \)-conversion. A \( \lambda \)-theory is any context closed equivalence on \( \Lambda \) containing the \( \beta \)-conversion.

Given an inequational theory \( T \) we write \( M \sqsubseteq_T N \) or \( T \vdash M \sqsubseteq N \) for \( (M,N) \in T \). Similarly, given a \( \lambda \)-theory \( T \), we write \( M =_T N \) or \( T \vdash M = N \) whenever \( (M,N) \in T \).

The set of all \( \lambda \)-theories, ordered by set theoretical inclusion, forms a complete lattice \( \Lambda T \) that has a rich mathematical structure, as shown by Salibra and his coauthors in their works [79, 63, 68].

**Definition 1.18.** A \( \lambda \)-theory (or an inequational theory) is called:

- consistent if it does not equate all \( \lambda \)-terms;
- extensional if it contains the \( \eta \)-conversion;
- sensible if it equates all unsolvables.

We denote by \( \lambda \) the least \( \lambda \)-theory, by \( \lambda \eta \) the least extensional \( \lambda \)-theory, by \( H \) the least sensible \( \lambda \)-theory, and by \( B \) the (sensible) \( \lambda \)-theory equating all \( \lambda \)-terms having the same Böhm tree. Given a \( \lambda \)-theory \( T \), we write \( T\eta \) for the least \( \lambda \)-theory containing \( T \cup \lambda \eta \).

Inequational theories are less ubiquitously studied in the literature, except when they capture some observational preorder as explained in the next section. However, they have been studied in full generality in connection with denotational models (see, e.g., [11]).

2. The Lambda Theories \( \mathcal{H}^+ \) and \( \mathcal{H}^* \)

Several interesting \( \lambda \)-theories are obtained via suitable observational preorders defined with respect to a set \( O \) of observables. This has been first done by Morris’s in his PhD thesis [69].

**Definition 2.1.** Let \( O \) be a non-empty subset of \( \Lambda \).
• The $O$-observational preorder is given by:
\[ M \sqsubseteq^O N \iff \forall C[-] . C[M] \in_D O \text{ entails } C[N] \in_D O, \]
where $M \in_D O$ means that there exists a $\lambda$-term $M'$ such that $M \rightarrow[^D] M' \in O$.

• The $O$-observational equivalence $M \equiv^O N$ is defined as $M \sqsubseteq^O N$ and $N \sqsubseteq^O M$.

In the rest of the section we will discuss the $\lambda$-theories $H^*$ and $H^+$ generated as observational equivalences by considering as observables the head normal forms and the $\beta$-normal forms, respectively, and the corresponding preorders\(^3\). In both cases we also recall the characterizations given in terms of extensional equivalences on Böhm-trees.

2.1. $H^*$: Böhm Trees and Infinite $\eta$-Expansions. The $\lambda$-theory $H^*$ has been defined by Wadsworth and Hyland as an observational equivalence in [88, 47], where they proved that it corresponds to the equational theory induced by Scott’s model $\mathcal{P}_\infty$. In the years, $H^*$ has become the most well studied $\lambda$-theory $[7, 44, 41, 77, 65, 16]$.

**Definition 2.2.** We let $\sqsubseteq_{H^*}$ be the $O$-observational preorder obtained by taking as $O$ the set of head normal forms and $H^*$ be the corresponding equivalence.

Notice that $M =_{H^*} N$ is equivalent to say that $M, N$ are not semi-separable. It is easy to check that $H^*$ is an extensional $\lambda$-theory. A first characterization of $H^*$ can be given in terms of maximal consistent extension (also known as Post-completion) of $H$, and such a maximality property extends to the corresponding inequational theory.

The following lemma is a generalization of $[7$, Thm. 16.2.6] that encompasses the inequational case.

**Lemma 2.3.** The preorder $\sqsubseteq_{H^*}$ and the equivalence $H^*$ are maximal among consistent sensible inequational theories and $\lambda$-theories, respectively.

**Proof.** Let $\sqsubseteq_T$ be an inequational theory such that $\sqsubseteq_{H^*} \subseteq \sqsubseteq_T$. This means that there exist $M, N$ such that $M \sqsubseteq_T N$ while $M \not\sqsubseteq_{H^*} N$. By Definition 2.2, there is a context $C[-]$ such that $C[M]$ has an hnf while $C[N]$ does not. By Theorem 1.8, there is a head context $H[-] = (\lambda x.[-])\overline{P}$ such that $H[C[M]] =_D I$ and $H[C[N]]$ is unsolvable. As $M \sqsubseteq_T N$ we get:
\[ I =_D H[C[M]] \sqsubseteq_T H[C[N]] =_T \Omega_3 \quad \text{for } \Omega_3 = \Delta_3 \Delta_3 \text{ and } \Delta_3 = \lambda x.xxx. \]
The rightmost equality $=_T$ holds because $\Omega_3$ is unsolvable and the inequational theory $\sqsubseteq_T$ is sensible. Since $\Omega_3 \sqsubseteq_{H^*} I$ and $\sqsubseteq_{H^*} \subseteq \sqsubseteq_T$, we obtain $\Omega_3 =_T I$ which leads to:
\[ I =_T \Omega_3 =_D \Omega_3 \Delta_3 =_T I \Delta_3 =_D \Delta_3. \]
Since $I$ and $\Delta_3$ are $\beta\eta$-distinct normal form, this contradicts the Böhm Theorem $[14]$. \[ \square \]

The characterization of $H^*$ in terms of trees requires the notion of “infinite $\eta$-expansion” of a Böhm-like tree. Intuitively, the Böhm-like tree $V$ is an infinite $\eta$-expansion of $U$, if it is obtained from $U$ by performing countably many possibly infinite $\eta$-expansions.

The classic definition is given in terms of tree extensions $[7$, Def. 10.2.10$]$; here we rather follow the coinductive approach introduced in $[59]$.

\(^3\)When considering these particular sets $O$ of observables it is not difficult to check that the relations $\sqsubseteq^O$ and $\equiv^O$ are actually inequational and $\lambda$-theories (cf. $[7$, Prop. 16.4.6$]$). The general case is treated in $[71]$. 

Definition 2.4. Given two Böhm-like trees $U$ and $V$, we define coinductively the relation $U \leq_\infty V$ expressing the fact that $V$ is a (possibly) infinite $\eta$-expansion of $U$. We let $\leq_\infty$ be the greatest relation between Böhm-like trees such that $U \leq_\infty V$ entails that

- either $U = V = \perp$,
- or (for some $i, k, m, n \geq 0$):
  
  $$U = \lambda x_1 \ldots x_n . x_i U_1 \ldots U_k \text{ and } V = \lambda x_1 \ldots x_n z_1 \ldots z_m . x_i V_1 \ldots V_k V'_1 \ldots V'_m$$
  
  where $\bar{x} \cap \text{FV}(x_i U_1 \ldots U_k) = \emptyset$, $U_j \leq_\infty V_j$ for all $j \leq k$ and $z_\ell \leq_\infty V'_\ell$ for all $\ell \leq m$.

Notice that in Barendregt’s book [7, Def. 10.2.10(iii)], the relation above is denoted by $\leq_\eta$. We prefer to use a different notation because we want to emphasize the possibly infinitary nature of such $\eta$-expansions.

Theorem 2.5 [7, Thm. 19.2.9]. Let $M, N \in \Lambda$.

(i) $M \subseteq_{H^*} N$ if and only if there are Böhm-like trees $U, V$ such that $BT(M) \leq_\infty U \leq_\perp V \geq_\infty BT(N)$.

(ii) $M =_{H^*} N$ if and only if there is a Böhm-like tree $U$ such that $BT(M) \leq_\infty U \geq_\infty BT(N)$.

In other words, $H^*$ equates all $\lambda$-terms whose Böhm trees are equal up to countably many (possibly) infinite $\eta$-expansions. From Theorem 1.11, it follows that the trees $U, V$ appearing in the statements above can always be chosen $\lambda$-definable (see [7, Ex. 10.6.7]).

Example 2.6.

1. The typical example is $I =_{H^*} J$, since clearly $BT(J)$ is an infinite $\eta$-expansion of $I$, so $BT(I) \leq_\infty BT(J)$ holds.

2. As a consequence, we get that $BT([I]_{n \in N}) \leq_\infty BT([J]_{n \in N})$ for $[I]_{n \in N} = [I, [I, [I, \ldots]]]$ and $[J]_{n \in N} = [J, [J, [J, \ldots]]]$.

3. For $M = \lambda xy . xx \Omega(Jx)$ and $N = \lambda xy . x(\lambda z_q w_0 . x(Jz_0)(Jw_0))yx$, we have $M \subseteq_{H^*} N$ (as shown in Figure 2) but $M \neq_{H^*} N$. As we will see in Section 2.2, it is possible to represent the subterm $\lambda z_q w_0 . x(Jz_0)(Jw_0)$ as $J_T x$, where $J_T$ is an infinite $\eta$-expansion of $I$ following a suitable tree $T$.

The point (2) shows that for proving $BT(M) \leq_\infty BT(N)$ one may need to perform denumerably many infinite $\eta$-expansions. Point (3) shows that for proving $M \subseteq_{H^*} N$, it may not be enough to infinitely $\eta$-expand $BT(M)$ to match the structure of $BT(N)$: one may need to perform infinite $\eta$-expansions on both sides and cut some subtrees of $BT(N)$.
Remark 2.7. From Theorem 2.5 and Definition 2.4 it follows that if $M \subseteq H$, $N$ and $M$ is solvable then also $N$ is solvable and $M, N$ have similar hnf’s.

2.2. The Infinite $\eta$-Expansion $J_T$. Wadsworth’s combinator $J$ is the typical example of an infinite $\eta$-expansion of the identity. However, there are many $\lambda$-terms $M$ that satisfy the property of being infinite $\eta$-expansions of the identity, namely $BT(I) \precsim \eta BT(M)$.

Recall from Section 1.6 that $|BT(M)|$ denotes the underlying tree of $BT(M)$.

Definition 2.8. Let $M \in \Lambda^\circ$ and $T \in T^\infty$. We say that $M$ is an infinite $\eta$-expansion of the identity following $T$ whenever $x \precsim \eta BT(Mx)$ and $[BT(Mx)] = T$ for any $x \in \text{Var}$.

For instance, $J$ follows the infinite unary tree $T$ corresponding to the map $T(\sigma) = 1$ for all $\sigma = \langle 0, \ldots, 0 \rangle$. We now provide a characterization of all such infinite $\eta$-expansions.

Proposition 2.9. For all $T \in T^\infty$, there exists a $\lambda$-term $J_T$ which is an infinite $\eta$-expansion of the identity following $T$ if and only if $T$ is recursive.

Proof. ($\Rightarrow$) By Theorem 1.11, $BT(J_Tx)$ is partial recursive and so is its underlying tree $T$. Since $x \precsim \eta BT(J_Tx)$, $BT(J_Tx)$ cannot have any occurrences of $\perp$ so $\text{dom}(T)$ is decidable.

($\Leftarrow$) We fix a bijective encoding of all finite sequences of natural numbers $\# : \mathbb{N}^{<\omega} \rightarrow \mathbb{N}$ which is effective in the sense that the code $\#((\sigma, n))$ is computable from $\#\sigma$ and $n$. We write $[\sigma]$ for the corresponding Church numeral $c_{#\sigma}$. Using a fixed point combinator $Y$, we define a $\lambda$-term $X \in \Lambda^\circ$ satisfying the following recursive equation (for all $\sigma \in \text{dom}(T)$):

$$X[\sigma] =_\beta \lambda z_1 \ldots z_m. x(X[\sigma,0]z_1) \cdots (X[\sigma,m - 1]z_m) \text{ where } m = T(\sigma).$$

(2.1)

(The existence of such a $\lambda$-term follows from the fact that $T$ is recursive, the effectiveness of the encoding $\#$ and Church’s Thesis.) We prove by coinduction that for all $\sigma \in \text{dom}(T)$, $X[\sigma]$ is an infinite $\eta$-expansion of the identity following $T|_\sigma$. Indeed, $X[\sigma]x$ is $\beta$-convertible to the $\lambda$-term of Equation 2.1. By coinductive hypothesis we get for all $i < T(\sigma)$ that $z_i \precsim \eta BT(X[\sigma,i]z_i)$ and $[BT(X[\sigma,i]z_i)] = T|_{\sigma,i}$. From this, we conclude that $x \precsim \eta BT(X[\sigma]x)$ and $[BT(X[\sigma]x)] = T$. Therefore, the $\lambda$-term $J_T$ we are looking for is $X[\varepsilon]$. \qed
2.3. $\mathcal{H}^+$: Böhm Trees and Their Finitary $\eta$-Expansions. Perhaps surprisingly, it turns out that $\mathcal{H}^+$ is not the first $\lambda$-theory that has been defined in terms of contextual equivalence. Indeed, Morris’s original extensional observational equivalence is the following.

**Definition 2.10.** Morris’s inequational theory $\sqsubseteq_{\mathcal{H}^+}$ is the $\mathcal{O}$-observational preorder obtained by taking as $\mathcal{O}$ the set $\text{NF}_\beta$ of $\beta$-normal forms. We denote by $\mathcal{H}^+$ the corresponding equivalence, which we call Morris’s $\lambda$-theory$^4$.

Notice that it is equivalent to take as observables the $\beta\eta$-normal forms, since $M \rightarrow_{\beta} \text{nf}_\beta(M)$ exactly when $M \rightarrow_{\beta\eta} \text{nf}_{\beta\eta}(M)$. From this, it follows that $\mathcal{H}^+$ is an extensional $\lambda$-theory. It is easy to show that $M \sqsubseteq_{\mathcal{H}^+} N$ entails $M \sqsubseteq_{\mathcal{H}^*} N$, therefore we have $\mathcal{H}^+ \subseteq \mathcal{H}^*$.

In [26], Coppo, Dezani-Ciancaglini and Zacchi defined a filter model having $\mathcal{H}^+$ as equational theory. Also $\mathcal{H}^+$ can be characterized via a suitable extensional equivalence between Böhm trees. Intuitively, the Böhm-like tree $U$ is a finitary $\eta$-expansion of $V$, if it is obtained from $V$ by performing countably many finite $\eta$-expansions.

**Definition 2.11.** Given two Böhm-like trees $U$ and $V$, we define coinductively the relation $U \leq^\eta_0 V$ expressing the fact that $V$ is a finitary $\eta$-expansion of $U$. We let $\leq^\eta$ be the greatest relation between Böhm-like trees such that $U \leq^\eta V$ entails that

- either $U = V = \bot$,
- or (for some $i, k, m, n \geq 0$):

  $$U = \lambda x_1 \ldots x_n.x_1U_1 \ldots U_k \quad \text{and} \quad V = \lambda x_1 \ldots x_n.z_1 \ldots z_m.x_1V_1 \ldots V_kQ_1 \ldots Q_m$$

  where $\mathcal{FV}(x_1U_1 \ldots U_k) = \emptyset$, $U_j \leq^\eta_0 V_j$ for all $j \leq k$ and $Q \in \text{NF}_\beta$ are such that $Q_\ell \rightarrow^\eta z_\ell$ for all $\ell \leq m$.

Two $\lambda$-terms $M, N$ are equivalent in $\mathcal{H}^+$ exactly when their Böhm trees are equal up to countably many $\eta$-expansions of finite depth.

**Theorem 2.12** [46, Thm. 2.6]. For $M, N \in \Lambda$, we have that $M =_{\mathcal{H}^+} N$ if and only if there exists a Böhm-like tree $U$ such that $\text{BT}(M) \leq^\eta_0 U \geq^\eta \text{BT}(N)$.

**Example 2.13.** Recall from Example 2.6(2) that $[\mathbf{I}]_{n \in \mathbb{N}} = [\mathbf{I}, [\mathbf{I}, [\mathbf{I}, \ldots]]]$ and define the sequence $[\mathbf{1}]_{n \in \mathbb{N}} = [\mathbf{1}, [\mathbf{1}, [\mathbf{1}, \mathbf{}]]]$ where $\mathbf{1}_n$ is defined on Page 8. From Definition 2.11 it follows $\text{BT}([\mathbf{I}]_{n \in \mathbb{N}}) \leq^\eta \text{BT}([\mathbf{1}]_{n \in \mathbb{N}})$ while, for instance, $\text{BT}([\mathbf{1}]_{n \in \mathbb{N}}) \not\leq^\eta \text{BT}([\mathbf{J}]_{n \in \mathbb{N}})$.

As a brief digression, notice that the $\lambda$-terms $[\mathbf{I}]_{n \in \mathbb{N}}$ and $[\mathbf{1}]_{n \in \mathbb{N}}$ can be used to show that $\mathcal{B}\eta \subseteq \mathcal{H}^+$. Indeed, for $M, N \in \Lambda$, $M \rightarrow^\eta_0 N$ entails that $\text{BT}(M)$ can be obtained from $\text{BT}(N)$ by performing at most one $\eta$-expansion at every position (see [7, Lemma 16.4.3]). However, to equate the Böhm trees of $[\mathbf{I}]_{n \in \mathbb{N}}$ and $[\mathbf{1}]_{n \in \mathbb{N}}$, at every level one needs to perform $\eta$-expansions of increasing depth and this is impossible in $\mathcal{B}\eta$ (as shown in [51]).

As proved in [18] by exploiting a revised Böhm-out technique, the following weak separation result holds. (For the interested reader a fully detailed proof will appear in [50].)

**Theorem 2.14** (Morris Separation). Let $M, N \in \Lambda$ such that $M \subseteq_{\mathcal{H}^*} N$ while $M \not\subseteq_{\mathcal{H}^+} N$. There exists a context $C[\_\_\_\_\_]$ such that $C[M] =_{\beta\eta} \mathbf{I}$ and $C[N] =_{\mathcal{B}} \mathbf{J}_T$ for some $T \in \mathbb{T}_\text{rec}^\infty$.

This allows to Morris-separate also $\lambda$-terms like $\mathbf{I}$ and $\mathbf{J}$ that are not semi-separable.

---

$^4$ The notation $\mathcal{H}^+$ for Morris’s $\lambda$-theory has been used in [67, 18, 51]. The same $\lambda$-theory is denoted $\mathcal{T}_{NP}$ in Barendregt’s book [7] and $\mathcal{N}$ in Paolini and Ronchi della Rocca’s one [77].
2.4. Extensional Approximants. As far as we know, in the literature there is no characterization of $\sqsubseteq_{\mathcal{H}^+}$ in terms of extensional equality between Böhm trees. However, Lévy in [60] provides a characterization in terms of “extensional approximants” of Böhm trees. Recall from Definition 1.15(2) that $\mathit{BT}^*(M)$ is the set of all finite approximants of $M$.

**Definition 2.15.** For $M \in \Lambda$, the set $\mathit{BT}^e(M)$ of all extensional (finite) approximants of $M$ is defined as follows:

$$\mathit{BT}^e(M) = \{ \eta t | t \in \mathit{BT}^*(M'), M' \to_{\eta} M \}.$$  

**Example 2.16.** The sets of extensional approximants of some notable $\lambda$-terms:

- $\mathit{BT}^e(\mathbf{I}) = \{ \bot, \mathbf{I}, \lambda x z_0. x \bot, \lambda x z_0. x(\lambda z_1.z_0 \bot), \lambda x z_0. x(\lambda z_1.z_0(\lambda z_2.z_1 \bot)), \ldots \}$,
- $\mathit{BT}^e(\mathbf{J}) = \mathit{BT}^e(\mathbf{I}) - \{ \mathbf{I} \}$.

(Here we decided to display those approximants having a regular shape, but also $\lambda \bot$-terms like $\lambda x z_0 z_1 z_2. x(\lambda w_0 w_1. z_0 w_0 \bot) z_1 \bot$ belong to these sets).

The following result is taken from [60] (see also Theorem 11.2.20 in [77]) and will be used in the proof of Corollary 4.18.

**Theorem 2.17.** For $M, N \in \Lambda$ we have $M \sqsubseteq_{\mathcal{H}^+} N$ if and only if $\mathit{BT}^e(M) \subseteq \mathit{BT}^e(N)$.

3. The Relational Graph Models

In this section we recall the definition of a relational graph model (rgm, for short). Individual examples of rgm’s have been previously studied in the literature as models of the $\lambda$-calculus [20, 65, 29, 49], of nondeterministic $\lambda$-calculi [21] and of resource calculi [66, 70]. However, the class of relational graph models was formally introduced in [67].

3.1. The Relational Semantics. Relational graph models are called relational since they are reflexive objects in the Cartesian closed category $\mathbf{MRel}$ [20], which is the Kleisli category of the finite multisets comonad $\mathit{M}_f(-)$ on $\mathbf{Rel}$. Since we do not use the underlying symmetric monoidal category, we present directly its Cartesian closed structure. Recall that the definitions and notations concerning multisets have been introduced in Subsection 1.2.

**Definition 3.1.** The category $\mathbf{MRel}$ is defined as follows:

- The objects of $\mathbf{MRel}$ are all the sets.
- A morphism from $A$ to $B$ is a relation from $\mathit{M}_f(A)$ to $B$; in other words, $\mathbf{MRel}(A, B) = \mathcal{P}(\mathit{M}_f(A) \times B)$.
- The identity of $A$ is the relation $\mathbf{Id}_A = \{ ([\alpha], \alpha) \mid \alpha \in A \} \in \mathbf{MRel}(A, A)$.
- The composition of $f \in \mathbf{MRel}(A, B)$ and $g \in \mathbf{MRel}(B, C)$ is defined by:

$$g \circ f = \{ (a, \gamma) \mid \exists k \in \mathbb{N}, \exists (a_1, \beta_1), \ldots, (a_k, \beta_k) \in f \text{ such that } a = a_1 + \cdots + a_k \text{ and } ([\beta_1, \ldots, \beta_k], \gamma) \in g \}.$$  

Given two sets $A_1, A_2$, we denote by $A_1 \& A_2$ their disjoint union ($\{1\} \times A_1 \cup \{2\} \times A_2$). Hereafter we adopt the following convention.

**Convention.** We consider the canonical bijection (also known as Seely isomorphism [13]) between $\mathit{M}_f(A_1) \times \mathit{M}_f(A_2)$ and $\mathit{M}_f(A_1 \& A_2)$ as an equality. As a consequence, we still denote by $(a_1, a_2)$ the corresponding element of $\mathit{M}_f(A_1 \& A_2)$.
Theorem 3.2. The category $\text{MRel}$ is a Cartesian closed category.

Proof. The terminal object $\top$ is the empty set $\emptyset$, and the unique element of $\text{MRel}(A, \emptyset)$ is the empty relation.

Given two sets $A_1$ and $A_2$, their categorical product in $\text{MRel}$ is their disjoint union $A_1 \& A_2$ and the projections $\pi_1, \pi_2$ are given by:

$$\pi_i = \{(i, a) \mid a \in A_i\} \in \text{MRel}(A_1 \& A_2, A_i), \text{ for } i = 1, 2.$$ 

It is easy to check that in this way we defined an exponentiation. Indeed, given $f \in \text{MRel}(B, A_1)$ and $g \in \text{MRel}(B, A_2)$, the corresponding morphism $(f, g) \in \text{MRel}(B, A_1 \& A_2)$ is given by:

$$\langle f, g \rangle = \{(b, (1, \alpha)) \mid (b, \alpha) \in f\} \cup \{(b, (2, \alpha)) \mid (b, \alpha) \in g\}.$$ 

Given two objects $A$ and $B$, the exponential object $A \Rightarrow B$ is $\mathcal{M}_f(A) \times B$ and the evaluation morphism is given by:

$$\text{ev}_{AB} = \{(([a, \beta], \alpha), \beta) \mid a \in \mathcal{M}_f(A) \text{ and } \beta \in B\} \in \text{MRel}((A \Rightarrow B) \& A, B).$$

Again, it is easy to check that in this way we defined an exponentiation. Indeed, given any set $C$ and any morphism $f \in \text{MRel}(C \& A, B)$, there is exactly one morphism $\Lambda(f) \in \text{MRel}(C, A \Rightarrow B)$ such that:

$$\text{ev}_{AB} \circ (\Lambda(f) \times \text{Id}_S) = f.$$ 

which is $\Lambda(f) = \{(c, (a, \beta)) \mid (c, a, \beta) \in f\}$. \qed

The category $\text{MRel}$ provides a simple example of a non-well-pointed category.

Theorem 3.3. No object $A \neq \top$ is well-pointed, so neither is $\text{MRel}$.

Proof. For every $A \neq \emptyset$, we can always find $f, g : A \rightarrow A$ such that $f \neq g$ and, for all $h : \top \rightarrow A$, $f \circ h = g \circ h$. Indeed, by definition of composition, $f \circ h = \{\omega, \alpha \mid \exists \beta_1, \ldots, \beta_k \in A, (\omega, \beta_i) \in h, ([\beta_1, \ldots, \beta_k], \alpha) \in f\}$, and similarly for $g \circ h$. Hence it is sufficient to choose $f = \{(a_1, \alpha)\}$ and $g = \{(a_2, \alpha)\}$ for $a_1, a_2$ different multisets with the same support. \qed

3.2. The Class of Relational Graph Models. The class of graph models constitutes a subclass of the continuous semantics [81] and is the simplest generalization of the Engeler and Plotkin’s construction [39, 74]. This class has been widely studied in the literature and has been used to prove several interesting results [10]. We recall that a graph models is given by a set $A$ and a total injection $i : \mathcal{P}_f(A) \times A \rightarrow A$, and induces $\mathcal{P}(A)$ as a reflexive object in the category of Scott’s domains and continuous functions. Therefore, a bijective $i$ does not induce automatically an isomorphism between $\mathcal{P}(A)$ and $\mathcal{P}(A) \Rightarrow \mathcal{P}(A)$. As shown in [10, §5.5], no graph model $\mathcal{G}$ can be extensional because $\models 1 \sqsubseteq I$ is never satisfied.

The definition of a relational graph model mimics the one of a graph model while replacing finite sets with finite multisets. As we will see, relational graph models capture a particular subclass of reflexive objects living in $\text{MRel}$.

Definition 3.4. A relational graph model $\mathcal{D} = (D, i)$ is given by an infinite set $D$ and a total injection $i : \mathcal{M}_f(D) \times D \rightarrow D$. We say that $\mathcal{D}$ is extensional when $i$ is bijective.

The equality $i(a, \alpha) = \beta$ indicates that the “arrow type” $a \rightarrow \alpha$ is equivalent to the type $\beta$. In particular, in an extensional relational graph model, every element of the model can be seen as an arrow. Keeping this intuition in mind, we adopt the notation below.
Notation 3.5. Given an rgm $D = (D, i)$, $a \in \mathcal{M}_f(D)$ and $\alpha \in D$, we write $a \rightarrow_i \alpha$ (or simply $a \rightarrow \alpha$, when $i$ is clear) as an alternative notation for $i(a, \alpha)$.

As shown in the next proposition, the reflexive object induced by a relational graph model $(D, i)$ is not some powerset of $D$ as in the case of regular graph models, but rather $D$ itself. This opens the way to define extensional reflexive objects.

Proposition 3.6. Given an rgm $D = (D, i)$ we have that:

(i) $D$ induces a reflexive object $(D, \text{App}, \lambda)$ where

$$\lambda = \{([(a, \alpha)], a \rightarrow_i \alpha) | a \in \mathcal{M}_f(D), \alpha \in D\} \in \mathcal{M}_{\mathcal{R}el}(D \Rightarrow D, D),$$

$$\text{App} = \{([a \rightarrow_i \alpha], (a, \alpha)) | a \in \mathcal{M}_f(D), \alpha \in D\} \in \mathcal{M}_{\mathcal{R}el}(D, D \Rightarrow D),$$

(ii) If moreover $D$ is extensional, then also the induced reflexive object is.

Proof. (ii) $\text{App} \circ \lambda = \{([(a, \alpha)], (a, \alpha)) | ([a \rightarrow \alpha], (a, \alpha)) \in \lambda, ([a \rightarrow \alpha], (a, \alpha)) \in \text{App}\} =\{([(a, \alpha)], (a, \alpha)) | a \in \mathcal{M}_f(D), \alpha \in D\} = \text{Id}_{\mathcal{M}_f(D) \times D} = \text{Id}_{D \Rightarrow D}$.

((iii)) If $i$ is bijective for every $D$ we have $\beta = a \rightarrow_i \alpha$ for some $a \in \mathcal{M}_f(D)$ and $\alpha \in D$. So $\lambda \circ \text{App} = \{([a \rightarrow \alpha], a \rightarrow \alpha) | ([a \rightarrow \alpha], (a, \alpha)) \in \text{App}, ([a \rightarrow \alpha], a \rightarrow \alpha) \in \lambda\} =\{([a \rightarrow \alpha], a \rightarrow \alpha) | a \in \mathcal{M}_f(D), \alpha \in D\} = \{([\beta], \beta) | \beta \in D\} = \text{Id}_D$.

3.3. Building Relational Graph Models by Completion. Relational graph models – just like the regular ones – can be built by performing the free completion of a partial pair.

Definition 3.7.

1. A partial pair $\mathcal{A}$ is a pair $(A, j)$ where $A$ is a non-empty set of elements (called atoms) and $j : \mathcal{M}_f(A) \times A \rightarrow A$ is a partial injection.

2. A partial pair $\mathcal{A}$ is called extensional when $j$ is a bijection between $\text{dom}(j)$ and $A$.

3. A partial pair $\mathcal{A}$ is called total when $j$ is a total function, and in this case $\mathcal{A}$ is a relational graph model.

Hereafter, we consider without loss of generality partial pairs $\mathcal{A}$ whose underlying set $A$ does not contain any pair of elements. In other words, we assume $(\mathcal{M}_f(A) \times A) \cap A = \emptyset$. This is not restrictive because partial pairs can be considered up to isomorphism.

Definition 3.8. The free completion $\overline{\mathcal{A}}$ of a partial pair $\mathcal{A}$ is the pair $(\overline{\mathcal{A}}, \overline{j})$ defined as: $\overline{\mathcal{A}} = \bigcup_{n \in \mathbb{N}} A_n$, where $A_0 = A$ and $A_{n+1} = (\mathcal{M}_f(A_n) \times A_n) - \text{dom}(j)) \cup A$; moreover

$$\overline{j}(a, \alpha) = \begin{cases} j(a, \alpha) & \text{if } (a, \alpha) \in \text{dom}(j), \\ (a, \alpha) & \text{otherwise.} \end{cases}$$

It is well known for graph models, and easy to check for relational graph models, that every $D$ is isomorphic to its own free completion $\overline{D} \cong D$. In particular, given a partial pair $\mathcal{A}$, we have that $\overline{\mathcal{A}} \cong \overline{\mathcal{A}}$. 
Proposition 3.9. If \( \mathcal{A} \) is an (extensional) partial pair, then \( \overline{\mathcal{A}} \) is an (extensional) rgm.

Proof. The proof of the fact that \( \overline{\mathcal{A}} \) is an rgm is analogous to the one for regular graph models \([10]\). It is easy to check that when \( j \) is bijective, also its completion \( \overline{j} \) is. \( \square \)

The following relational graph models are built by free completion and will be running examples in the next sections.

Example 3.10. Some examples of relational graph model:

- \( \mathcal{E} = [\mathbb{N}, \emptyset] \) was introduced in \([49]\),
- \( \mathcal{D}_\omega = \{ \llbracket *, \rrbracket, \llbracket (\omega, \star) \mapsto \star \rrbracket \} \) was first defined (up to isomorphism) in \([20]\),
- \( \mathcal{D}_* = \{ \llbracket *, \rrbracket, \llbracket (\star, *, \star) \mapsto \star \rrbracket \} \) was introduced in \([67]\).

Notice that \( \mathcal{D}_\omega \) and \( \mathcal{D}_* \) are extensional, while \( \mathcal{E} \) is not.

3.4. Categorical Interpretation. We now show how \( \lambda \)-terms and Böhm trees can be interpreted in a relational graph model, and we review their main properties.

Recall that notions and notations concerning multisets have been introduced in Section 1.2. Given two \( n \)-uples \( \vec{a}, \vec{b} \in \mathcal{M}_f(A)^n \) we write \( \vec{a} + \vec{b} \) for \( (a_1 + b_1, \ldots, a_n + b_n) \in \mathcal{M}_f(A)^n \).

Definition 3.11. Let \( \mathcal{D} \) be an rgm, \( M \in \Lambda \) and \( \text{FV}(M) \subseteq \{ x_1, \ldots, x_n \} \). The categorical interpretation of \( M \) in \( \mathcal{D} \) w.r.t. \( \vec{x} \) is the relation \( |M|_{\vec{x}}^D \subseteq \mathcal{M}_f(D)^n \times D \) defined by:

i. \[ |x_1|_{\vec{x}}^D = \{ (\omega, \ldots, \omega, [\alpha], \omega, \ldots, \omega), \alpha \mid \alpha \in D \}, \] where \( [\alpha] \) stands in \( i \)-th position.

ii. \[ |\lambda \gamma . N|_{\vec{x}}^D = \{ (\vec{a}, a \rightarrow_i \alpha) \mid ((\vec{a}, \alpha), \alpha) \in |N|_{\vec{x}}^D \} \] where we take \( y \notin \vec{x} \) by \( \alpha \)-conversion.

iii. \[ |PQ|_{\vec{x}}^D = \{ (\vec{a}_0 + \cdots + \vec{a}_k), \alpha \mid \exists \alpha_1, \ldots, \alpha_k \in D \text{ such that } (\vec{a}_0, [\alpha_1, \ldots, \alpha_k] \rightarrow_i \alpha) \in |P|_{\vec{x}}^D \text{ and } (\vec{a}_j, \alpha_j) \in |Q|_{\vec{x}}^D \text{ for all } 1 \leq j \leq k \}. \]

This definition extends to \( \lambda \bot \)-terms \( M \) by setting \( |\bot|_{\vec{x}}^D = \emptyset \) and to Böhm trees of \( \lambda \)-terms by interpreting all their finite approximants, namely by setting \( |\text{BT}(M)|_{\vec{x}}^D = \bigcup_{t \in \text{BT}^*(M)} |t|_{\vec{x}}^D \).

It is easy to check that the definition above is an inductive characterization of the usual categorical interpretation of \( \lambda \)-terms as morphisms of a Cartesian closed category.

Convention. From now on, whenever we write \( |M|_{\vec{x}}^D \) we always assume that \( \text{FV}(M) \subseteq \vec{x} \).

When \( M \) is a closed \( \lambda \)-term we consider \( |M|_{\vec{x}}^D \) simply as a subset of \( D \). In all our notations we omit the model \( \mathcal{D} \) when it is clear from the context.

Example 3.12. Let \( \mathcal{D} \) be any rgm. Then we have:

1. \[ |1|_{\vec{x}}^D = \{ [\alpha] \rightarrow \alpha \mid \alpha \in D \} \] and

2. \[ |0|_{\vec{x}}^D = \{ [\alpha \rightarrow a \rightarrow \alpha] \rightarrow \alpha \mid \alpha \in D, a \in \mathcal{M}_f(D) \}, \text{ thus:} \]

3. \[ |J|_{\vec{x}}^D = \{ [\alpha] \rightarrow \alpha \mid \alpha \in D' \} \subseteq |1|_{\vec{x}}^D \subseteq |1|_{\vec{x}}^D, \text{ where } D' \text{ is the smallest subset of } D \text{ satisfying:} \]

- if \( \alpha \in D \) then \( \omega \rightarrow \alpha \rightarrow D' \); if \( \alpha \in D \) and \( a \in \mathcal{M}_f(D') \) then \( a \rightarrow \alpha \rightarrow D' \),

4. \[ |\Delta|_{\vec{x}}^D = \{ [\alpha + [\alpha \rightarrow a]] \rightarrow \alpha \mid \alpha \in D, a \in \mathcal{M}_f(D) \} \] therefore:

5. \[ |\Omega|_{\vec{x}}^D = |\bot|_{\vec{x}}^D = \emptyset, \]

6. \[ |\lambda \alpha . x \Omega|_{\vec{x}}^D = \{ [\omega \rightarrow \alpha] \rightarrow \alpha \mid \alpha \in D \}. \]

Consider the relational graph models \( \mathcal{D}_\omega \) and \( \mathcal{D}_* \) from Example 3.10. From the calculations above it follows that \( |1| = |1| \) in both \( \mathcal{D}_\omega \) and \( \mathcal{D}_* \), but \( |1|_{\vec{x}}^D = |1|_{\vec{x}}^D \), while \( \star \in |1|_{\vec{x}}^D - |1|_{\vec{x}}^D \).
3.5. **Soundness.** Relational graph models satisfy the following substitution property and are sound models of λ-calculus in the sense that they equate all β-convertible λ-terms.

**Lemma 3.13** (Substitution). Let $M, N \in \Lambda$ and $D$ be an rgm. For $\vec{a} \in \mathcal{M}_f(D)^n$ and $\alpha \in D$ we have that $(\vec{a}, \alpha) \in [M\{N/y]\]_x$ if and only if there exist $b = [\beta_1, \ldots, \beta_k] \in \mathcal{M}_f(D)$ and $\vec{a}_0, \ldots, \vec{a}_k \in \mathcal{M}_f(D)^n$ such that $(\vec{a}_\ell, \beta_\ell) \in [N]_x^D$, for $1 \leq \ell \leq k$, $((\vec{a}_0, b), \alpha) \in [M]_x^D$ and $\vec{a} = \sum_{\ell=0}^k \vec{a}_\ell$.

**Proof.** We proceed by induction on $M$, the only interesting case being $M = PQ$.

$(\Rightarrow)$ We know that $(\vec{a}, \alpha) \in [M\{N/y]\]_x$ if and only if there are $\gamma_1, \ldots, \gamma_k$ and a decomposition $\vec{a} = \sum_{\ell=0}^k \vec{a}_\ell$ such that $(\vec{a}^0, [\gamma_1, \ldots, \gamma_k] \rightarrow \alpha) \in [P\{N/y\}]_x$ and $(\vec{a}^\ell, \gamma_\ell) \in [Q\{N/y\}]_x$ for $1 \leq \ell \leq k$. By applying the induction hypothesis to the former assumption, we get $b^0 = [\beta_1, \ldots, \beta_k]$ and a decomposition $\vec{a}^0 = \sum_{j=0}^m \vec{a}_j^0$ such that $((\vec{a}_j^0, b^\ell), [\gamma_1, \ldots, \gamma_k] \rightarrow \alpha) \in [P]_x^y$ and $(\vec{a}_j^0, \gamma_j) \in [N]_x$ for $1 \leq j \leq m$. From the latter, for each $\ell = 1, \ldots, k$ we get $b^\ell = [\beta_1, \ldots, \beta_k^\ell]$ and a decomposition $\vec{a}^\ell = \sum_{j=0}^{k_\ell} \vec{a}_j^\ell$ such that $((\vec{a}_j^\ell, b^\ell), \gamma_j) \in [Q]_x^y$ and $(\vec{a}_j^\ell, \gamma_j^\ell) \in [N]_x$ for $1 \leq j \leq k_\ell$. We conclude that $((\sum_{\ell=0}^k \vec{a}_\ell^\ell, \sum_{\ell=0}^k b^\ell), \alpha) \in [PQ]_x^y$.

$(\Leftarrow)$ By analogue calculations. \hfill \Box

**Lemma 3.14** (Monotonicity). Let $D$ be an rgm, and $M, N \in \Lambda$. If $[M]_x^D \subseteq [N]_x^D$ then for all contexts $C[-]$ we have $[C[M]]_x^D \subseteq [C[N]]_x^D$.

**Proof.** Notice that, by the Convention above, we assume $\text{FV}(M) \cup \text{FV}(N) \cup \text{FV}(C[-]) \subseteq \vec{x}$. The result follows by a straightforward induction on $C[-]$.

**Theorem 3.15** (Soundness). Let $M, N \in \Lambda$ and $D$ be a relational graph model. If $M =_\beta N$ then $[M]_x^D = [N]_x^D$.

**Proof.** From the substitution lemma and Lemma 3.14 we have that $M \rightarrow_\beta M'$ entails $[M]_x = [M']_x$. By Church Rosser $M =_\beta N$ if and only if they have a common reduct $P$ such that $M \rightarrow_\beta P$ and $N \rightarrow_\beta P$. Summing up, we have $[M]_x = [P]_x = [N]_x$.

**Definition 3.16.**

- The λ-theory induced by a relational graph model $D$ is defined by
  \[ \text{Th}(D) = \{(M, N) \in \Lambda \times \Lambda \mid [M]_x = [N]_x\} \].
  We write $D \models M = N$ for $(M, N) \in \text{Th}(D)$.
- Similarly, the inequational theory induced by $D$ is given by
  \[ \text{Th}_\subseteq(D) = \{(M, N) \in \Lambda \times \Lambda \mid [M]_x \subseteq [N]_x\} \].
  We write $D \models M \subseteq N$ for $(M, N) \in \text{Th}_\subseteq(D)$.
- An rgm $D$ is called $\mathcal{O}$-fully abstract when $D \models M = N$ if and only if $M \equiv^\mathcal{O} N$.
- $D$ is inequationally $\mathcal{O}$-fully abstract when $D \models M \subseteq N$ if and only if $M \equiv^\mathcal{O} N$.
- We say that a λ-theory (resp. inequational theory) $T$ is representable by a relational graph model if there exists an rgm $D$ such that $\text{Th}(D) = T$ (resp. $\text{Th}_\subseteq(D) = T$).
- We say that a λ-theory (resp. inequational theory) is a (resp. inequational) relational graph theory if it is represented by some relational graph model.

**Lemma 3.17.** Let $D$ be an rgm.

(i) If $M \rightarrow_\eta N$ then $[N]_x^D \subseteq [M]_x^D$,
(ii) $D$ is extensional if and only if $\lambda \eta \subseteq \text{Th}(D)$.
Proof. (i) By inspecting their interpretations (Example 3.12(1-2)) it is clear that \(|1| \subseteq |I|\). For all \(N \in \Lambda\), \(D \models 1N \subseteq 1N\) (monotonicity) which entails \(D \models \lambda x.Nx \subseteq N\) (soundness).

(ii) By monotonicity \(\lambda \eta \subseteq \text{Th}(D)\) if and only if \(D \models 1 = I\). As above, we know that \(D \models 1 \subseteq I\) holds. The other inclusion holds if and only if for all \(\alpha \in D\) there exist \(a, \beta\) such that \(i(a, \beta) = \alpha\) if and only if \(i\) is bijective.

As a consequence, the \(\lambda\)-theories induced by relational graph models and by ordinary graph models are different, since no graph model is extensional.

4. Quantitative Properties and Approximation Theorem

Every relational graph model can be presented as a type system. The interpretation of a \(\lambda\)-term \(M\) is given by the set of all pairs \((\Gamma, \alpha)\) such that \(\Gamma \vdash D M : \alpha\) is derivable in the system. Such a logical interpretation turns out to be equivalent to the categorical one (Theorem 4.8). This presentation exposes the quantitative nature of the relational semantics and allows to provide a combinatorial proof of the Approximation Theorem (Theorem 4.16).

4.1. Relational Graph Models as Type Systems. The types of the system associated to a relational graph model \(D = (D, i)\) are the elements of the underlying set \(D\) themselves. We recall from Notation 3.5 that \(a \to \alpha\) denotes the element \(i(a, \alpha)\) which belongs to \(D\).

**Definition 4.1.** An environment for \(D\) is a map \(\Gamma : \text{Var} \to M_1(D)\) such that \(\text{supp}(\Gamma) = \{ x \in \text{Var} \mid \Gamma(x) \neq \omega \}\) is finite. The set of all environments for \(D\) is denoted by \(\text{Env}_D\).

We write \(x_1 : a_1, \ldots, x_n : a_n\) for the environment \(\Gamma\) such that \(\Gamma(x_i) = a_i\) if \(1 \leq i \leq n\) and \(\Gamma(y) = \omega\) otherwise. When \(\text{supp}(\Gamma) = \emptyset\) the environment \(\Gamma\) is just omitted.

**Definition 4.2.** Given \(\Gamma, \Delta \in \text{Env}_D\) we define the environment \(\Gamma + \Delta\) by setting \((\Gamma + \Delta)(x) = \Gamma(x) + \Delta(x)\) for all \(x \in \text{Var}\).

A (type) judgment is a triple \((\Gamma, M, \alpha)\) such that \(\Gamma \vdash D M : \alpha\), or simply \(\Gamma \vdash M : \alpha\) whenever \(D\) is clear from the context.

**Definition 4.3.** Let \(D\) be a relational graph model. The inference rules of the type system \(\vdash_D\) for \(\Lambda_\perp\) associated with \(D\) are given in Figure 4.

We remark that these type systems are relevant since the weakening is not available. Indeed, the rule \(\text{var}\) does not allow a generic environment \(\Gamma, x : [\alpha]\) and the sum of contexts in \(\text{app}\) takes multiplicities into account. The types are strict in the sense that multisets may only appear at the left hand-side of an arrow. In particular, no \(\perp\)-term can have type \(\omega\).

The number \(n\) appearing in the rule \(\text{app}\) can be 0. So we have the inference rule

\[
\frac{\Gamma \vdash \lambda x. M : \alpha}{\Gamma \vdash MN : \alpha}
\]

(4.1)
for every $N \in \Lambda_\perp$. For example, even if $\Omega$ is not typable in the system associated with any relational graph model, the following derivation is always possible for every $\alpha \in D$: \[
 x: [\omega \to \alpha] \vdash_p x: \omega \to \alpha \\
 x: [\omega \to \alpha] \vdash_p x \Omega: \alpha \\
 \vdash_p \lambda x. x \Omega: [\omega \to \alpha] \to \alpha
\]

Hereafter, when writing $\Gamma \vdash_p M : \alpha$, we intend that such a judgment is derivable. We write $\pi \triangleright \Gamma \vdash_p M : \alpha$ to indicate that $\pi$ is a derivation tree of the judgment $\Gamma \vdash_p M : \alpha$.

**Definition 4.4.** Let $\pi, \pi'$ be two derivation trees. We set $\pi \simeq \pi'$ if and only if the trees obtained from $\pi$ and $\pi'$ by removing the $\lambda \perp$-terms from each of their nodes coincide.

**Example 4.5.** Let $\pi$ and $\pi'$ be the following derivation trees:
\[
 x: [\alpha] \vdash_p x: \alpha \\
 x: [\alpha] \vdash_p \lambda y. x: \omega \to \alpha \\
 x: [\alpha] \vdash_p (\lambda y. x) z: \alpha \\
 x: [\alpha] \vdash_p (\lambda y. x) \mathbf{K}: \alpha
\]

We have $\pi \simeq \pi'$ because once all $\lambda \perp$-terms are erased they both become like this:
\[
 x: [\alpha] \vdash_p : \alpha \\
 x: [\alpha] \vdash_p : \omega \to \alpha \\
 x: [\alpha] \vdash_p : \alpha
\]

From an intuitive perspective, the equivalence $\pi \simeq \pi'$ says that $\pi$ and $\pi'$ are roughly the same derivation tree (but it can possibly be used to type distinct $\lambda \perp$-terms).

**Lemma 4.6.** Let $\mathcal{D}$ be an rgm. If $\Gamma \vdash_p M : \alpha$ then $\text{supp}(\Gamma) \subseteq \text{FV}(M)$.

**Proof.** By a straightforward induction on the derivation of the judgment.

As shown by the first derivation of Example 4.5, the inclusion in Lemma 4.6 can be strict, indeed we have $x: [\alpha] \vdash (\lambda y.x) z: \alpha$ and $\text{supp}(x: [\alpha]) = \{x\} \subseteq \text{FV}(\lambda y.x) z$. In general, one should realize that whenever $\pi \triangleright \Gamma \vdash M : \alpha$ and $\text{supp}(\Gamma) \subseteq \text{FV}(M)$ then along $\pi$ some subterm $N$ of $M$ comes in argument position and is not actually typed, as in (4.1).

We could formalize the type systems $\vdash_p$ in a style more similar to traditional intersection type systems (as in [72]), in order to expose clearly the intuition of relational graph models as resource-sensitive versions of filter models [9, Part III], not only of graph models. We followed that approach in [67] and [78], where the multisets occurring in the types were actually denoted as non-idempotent intersections and an explicit conversion rule
\[
\Gamma \vdash_p M : \beta \frac{\beta \simeq \alpha}{\Gamma \vdash_p M : \alpha} \text{ eq}
\]

was available in the system. Since such a presentation does not change the expressive power of the systems, but complicates the technical proofs (as it obliges to consider the possible commutations of the rule $\text{eq}$ along a given derivation $\pi$) we decided to avoid it here.
4.2. Logical Interpretation. The type system associated to a relational graph model $\mathcal{D}$ provides an alternative way to define the interpretation of a $\lambda\perp$-term. This logical/type-theoretical approach is rather common and fits in the tradition of filter models [9, Part III].

**Definition 4.7.** Let $\mathcal{D}$ be an rgm and $M \in \Lambda_{\perp}$. The logical interpretation of $M$ in $\mathcal{D}$ is: 

$$\llbracket M \rrbracket^\mathcal{D} = \{ (\Gamma, \alpha) \in \text{Env}_\mathcal{D} \times D \mid \Gamma \vdash_{\mathcal{D}} M : \alpha \}. $$

When $\mathcal{D}$ is clear from the context we write $\llbracket M \rrbracket$, and when $M$ is closed we consider $\llbracket M \rrbracket \subseteq D$. This definition extends to Böhm trees of $\lambda$-terms like Definition 3.11.

The interpretation of a $\lambda\perp$-term cannot be just the set of its types as in the case of filter models. This is related with the fact that $\text{MRel}$ is not well-pointed (see Section 4.3).

We now show that the logical interpretation $\llbracket - \rrbracket^\mathcal{D}$ is equivalent to the categorical one $\llbracket - \rrbracket$ in the sense that they induce the same (in)equalities between $\lambda$-terms.

**Theorem 4.8 (Semantic Equivalence).** Let $M \in \Lambda$ and $\text{FV}(M) \subseteq \{x_1, \ldots, x_n\}$. Then

(i) $\llbracket M \rrbracket^\mathcal{D} = \{ ((x_1 : a_1, \ldots, x_n : a_n), \alpha) \in \text{Env}_\mathcal{D} \times D \mid ((a_1, \ldots, a_n), \alpha) \in \llbracket M \rrbracket \}$,

(ii) $\llbracket M \rrbracket^\mathcal{D} = \{ ((\Gamma(x_1), \ldots, \Gamma(x_n)), \alpha) \in \mathcal{M}_t(D)^n \times D \mid (\Gamma, \alpha) \in \llbracket M \rrbracket \}$.

**Proof.** (i) It is enough to prove that $\Gamma \vdash M : \alpha$ if and only if $((\Gamma(x_1), \ldots, \Gamma(x_n), \alpha)) \in \llbracket M \rrbracket$ and $\text{supp}(\Gamma) \subseteq \{x_1, \ldots, x_n\}$. We proceed by induction on $M$.

**Case** $M = x_i$. By Definition 4.3 we have $\Gamma \vdash x_i : \alpha$ if and only if $\Gamma = x_i : [\alpha]$. Thus, we have $((\Gamma(x_1), \ldots, \Gamma(x_n), \alpha)) = ((\omega, \ldots, \omega, [\alpha], \omega, \ldots, \omega), \alpha) \in \llbracket x_i \rrbracket$ by Definition 3.11(i).

**Case** $M = \lambda y.P$. By Definition 4.3 we have that $\Gamma \vdash \lambda y.P : \alpha$ holds exactly when $\Gamma, y : a \vdash P : \alpha$. By induction hypothesis this is equivalent to ask that $\text{supp}(\Gamma) \subseteq \{x_1, \ldots, x_n\}$ and $((\Gamma(x_1), \ldots, \Gamma(x_n), a, \alpha) \in \llbracket P \rrbracket_{\mathcal{D},y}$ which holds whenever $((\Gamma(x_1), \ldots, \Gamma(x_n), a) \rightarrow \alpha) \in \llbracket \lambda y.P \rrbracket_{\mathcal{D},y}$ by Definition 3.11(ii).

**Case** $M = PQ$. By Definition 4.3 we have $\Gamma \vdash PQ : \alpha$ if and only if $\Gamma_0 \vdash P : [\beta_1, \ldots, \beta_k] \rightarrow \alpha$ and $\Gamma_1 \vdash Q : \beta_i$ for all $1 \leq i \leq k$ where $\Gamma = \sum_{\alpha=0}^{\mathcal{D}} \Gamma_i$ and $\Gamma_1, \ldots, \Gamma_k \in D$. By induction hypothesis this is equivalent to require that $\text{supp}(\Gamma_i) \subseteq \{x_1, \ldots, x_n\}$ for all $0 \leq i \leq k$, $((\Gamma_0(x_1), \ldots, \Gamma_0(x_n)), [\beta_1, \ldots, \beta_k] \rightarrow \alpha) \in \llbracket P \rrbracket$ and $((\Gamma_j(x_1), \ldots, \Gamma_j(x_n), \beta_j) \in \llbracket Q \rrbracket$ for all $1 \leq j \leq k$. By Definition 3.11(iii), this is equivalent to $((\Gamma(x_1), \ldots, \Gamma(x_n), \alpha) \in \llbracket PQ \rrbracket$.

(II) This point follows since every element $((a_1, \ldots, a_n), \alpha) \in \mathcal{M}_t(D)^n \times D$ has the form $((\Gamma(x_1), \ldots, \Gamma(x_n)), \alpha)$ for $\Gamma = x_1 : a_1, \ldots, x_n : a_n$.

Q.E.D.

**Corollary 4.9.** Let $\mathcal{D}$ be an rgm. Let $M, N \in \Lambda$ such that $\text{FV}(MN) \subseteq \{x_1, \ldots, x_n\}$. Then

$$\mathcal{D} \models M \subseteq N \iff \llbracket M \rrbracket^\mathcal{D} \subseteq \llbracket N \rrbracket^\mathcal{D} \iff \llbracket M \rrbracket^\mathcal{D} \subseteq \llbracket N \rrbracket^\mathcal{D}.$$ 

4.3. On the choice of the interpretation. The categorical interpretation of a $\lambda$-term $M$ in a reflexive object $\mathcal{D}$ gives a morphism $\llbracket M \rrbracket : D^g \rightarrow D$ such that $\text{Th}(\mathcal{D})$ is a $\lambda$-theory. If the category is well-pointed, like Scott’s continuous semantics, then it is equivalent to interpret $M$ as a point of $D$ through a valuation $\rho : \text{Var} \rightarrow D$, namely $\llbracket M \rrbracket_\rho : \top \rightarrow D$ [7, §5.5].

For this reason, in the context of graph and filter models, it became standard to consider the interpretation of $M$ as an element of the domain and, when presented like a type system, as the set of its types [10, 26, 76, 77]. As shown by Koymans in [54], when the category is not well-pointed, points are no more suitable for interpreting $\lambda$-terms since the induced equality is not a $\lambda$-theory because of the failure of the $\xi$-rule [83]. In the algebraic terminology, the
there exists \( \pi \). We introduce some auxiliary notions that will be useful in the subsequent proofs.

We proceed by structural induction on \( \mathcal{D} \) and we provide a measure that decreases whenever any occurrence of a \( \beta \)-reduction is contracted.

Hence the judgment \( \sum i=0 \Gamma_i \vdash M\{N/x\} : \alpha \) holds exactly when they are equal under the valuation \( x \mapsto \pi_x^{\text{Var}} \) sending \( x \) to the corresponding projection. By applying this fact to the logical interpretation given in [72], we recover Definition 4.7 and this justifies Theorem 4.8 from a broader perspective. See [20, 83, 64] for more detailed discussions on well-pointedness.

4.4. Quantitative Properties. We show some quantitative properties satisfied by the type systems issued from a relational graph model. This quantitative behavior was first noticed by de Carvalho while studying the relational model \( E \) and linear head reduction [30]. Our statements are rather a more refined version\(^5\) of the ones appearing in [72].

Until the end of the section, the symbol \( \vdash \) refers to any fixed relational graph model. We introduce some auxiliary notions that will be useful in the subsequent proofs.

Definition 4.10. Let \( M, N \in \Lambda \) and \( \mathcal{D} \) be an rgm.

- Given \( \pi_0 \vdash \Gamma \vdash M : [\beta_1, \ldots, \beta_n] \rightarrow \alpha \) and \( \pi_i \vdash \Delta_i \vdash N : \beta_i \) for all \( 1 \leq i \leq n \), we let \( \text{App}(\pi_0, \{\pi_i\}_{i=0}^n) \) be the derivation tree of \( \Gamma + \sum_{i=1}^n \Delta_i \vdash MN : \alpha \) obtained by applying the rule \text{app} to those premises.

- Similarly, given \( \pi \vdash \Gamma, x : a \vdash M : \beta \) we define \( \text{Lam}(x, \pi) \) as the derivation obtained by applying the rule \text{lamb} to the derivation \( \pi \).

Let \( \#\text{app}(\pi) \) be the number of instances of the rule \text{app} that occur in the derivation \( \pi \).

Lemma 4.11 (Weighted Substitution Lemma). Let \( M, N \in \Lambda \). Consider some derivations \( \pi_0 \vdash \Gamma_0, x : [\beta_1, \ldots, \beta_n] \vdash M : \alpha \) for \( n \in \mathbb{N} \) and \( \pi_i \vdash \Gamma_i \vdash N : \beta_i \) for all \( 1 \leq i \leq n \). Then there exists \( \pi \vdash \sum_{i=0}^n \Gamma_i \vdash M\{N/x\} : \alpha \) such that \( \#\text{app}(\pi) = \sum_{i=0}^n \#\text{app}(\pi_i) \).

Proof. We proceed by structural induction on \( M \).

- Case \( M = \bot \). This case is vacuous, as \( \bot \) cannot be typed.
- Case \( M = y \neq x \). Then \( \pi_0 \vdash \Gamma_0, x : [\beta_1, \ldots, \beta_n] \vdash y : \alpha \) entails \( n = 0 \) and \( \Gamma_0 = y : \alpha \).

Hence the judgment \( \sum_{i=0}^n \Gamma_i \vdash M\{N/x\} : \alpha \) is nothing but \( y : \alpha \vdash y : \alpha \) and we can take \( \pi = \pi_0 \). Clearly we have that \( \#\text{app}(\pi) = 0 = \#\text{app}(\pi_0) = \sum_{i=0}^n \#\text{app}(\pi_i) \).

- Case \( M = x \). Then \( \Gamma_0, x : [\beta_1, \ldots, \beta_n] \vdash x : \alpha \) implies that \( n = 1, \beta_1 = \alpha \) and \( \Gamma_0 \) is empty. Hence the judgment \( \sum_{i=0}^n \Gamma_i \vdash M\{N/x\} : \alpha \) is just \( \Gamma_1 \vdash N : \alpha \) and we can take \( \pi = \pi_1 \). Therefore we have \( \#\text{app}(\pi) = \#\text{app}(\pi_1) = \sum_{i=0}^n \#\text{app}(\pi_i) \).

- Case \( M = \lambda y.P \). Then there is a derivation \( \pi'_0 \) such that \( \pi_0 \) has the form

\[
\pi'_0 \vdash \Gamma_0, y : [\alpha_1, \ldots, \alpha_n], x : [\beta_1, \ldots, \beta_n] \vdash M : \alpha' \\
\Gamma_0, x : [\beta_1, \ldots, \beta_n] \vdash \lambda y.M : [\alpha_1, \ldots, \alpha_n] \rightarrow \alpha'
\]

\(^5\) Indeed, the authors of [72] just consider the head reduction strategy and take as measure the size of the whole derivation tree. We show that it is the number of application rules that actually decreases along head reduction and we provide a measure that decreases whenever any occurrence of a \( \beta \)-reduction is contracted.
for $\alpha = [\alpha_1, \ldots, \alpha_n] \rightarrow \alpha'$. Notice that $\#app(\pi'_0) = \#app(\pi_0)$. By induction hypothesis, there exists a derivation $\pi'$ such that

$$\pi' \vdash (\Gamma_0, y : [\alpha_1, \ldots, \alpha_n]) + \sum_{i=1}^{n} \Gamma_i \vdash M\{N/x\} : \alpha'$$

(4.2)

with $\#app(\pi') = \#app(\pi'_0) + \sum_{i=1}^{n} \#app(\pi) = \sum_{i=0}^{n} \#app(\pi)$. By Lemma 4.6 we have $\text{supp}(\Gamma_i) \subseteq \text{FV}(N)$ for all $1 \leq i \leq n$. By $\alpha$-conversion we assume $y \notin \text{FV}(N)$, thus $y \notin \text{supp}(\Gamma_i)$ for all $i$. So the judgment in (4.2) is in fact $\sum_{i=0}^{n} \Gamma_i, y : [\alpha_1, \ldots, \alpha_n] \vdash M\{N/x\} : \alpha'$. We can then take $\pi = \text{Lam}(y, \pi') \vdash \sum_{i=0}^{n} \Gamma_i \vdash \lambda y.M\{N/x\} : [\alpha_1, \ldots, \alpha_n] \rightarrow \alpha'$. The thesis is proved since $\lambda y.M\{N/x\} = (\lambda y.M)\{N/x\}$ and $\#app(\pi) = \#app(\pi') = \sum_{i=0}^{n} \#app(\pi)$.

**Case $M = PQ$.** Then there are derivations $\pi_{00}, \pi_{0i}$ such that $\pi_0$ has the form

$$\pi_{00} \vdash \Gamma_{00}, x : [\beta_j]_{j \in I_0} \vdash P : [\gamma_1, \ldots, \gamma_k] \rightarrow \alpha \quad \pi_{0i} \vdash \Gamma_{0i}, x : [\beta_j]_{j \in I_i} \vdash Q : \gamma_i \text{ for all } 1 \leq i \leq k$$

where $k \in \mathbb{N}$, $\Gamma_0 = \sum_{i=0}^{k} \Gamma_{0i}$ and $\{I_i\}_{i=0}^{k}$ is a partition of the set $\{1, \ldots, n\}$. By induction hypothesis we get a derivation $\pi'_0 \vdash \Gamma_{00} + \sum_{j \in I_0} \sum_{i=1}^{n} \Gamma_{j} \vdash P\{N/x\} : [\gamma_1, \ldots, \gamma_k] \rightarrow \alpha$ such that $\#app(\pi_{00}) = \#app(\pi_0) + \sum_{j \in I_0} \#app(\pi_{j})$. Also, for all $1 \leq i \leq k$ the induction hypothesis provides a derivation $\pi'_i \vdash \Gamma_{0i} + \sum_{j \in I_i} \Gamma_{j} \vdash Q\{N/x\} : \gamma_i$ such that $\#app(\pi'_i) = \#app(\pi_{0i}) + \sum_{j \in I_i} \#app(\pi_{j})$.

We take $\pi = \text{App}(\pi'_0, \{\pi'_i\}_{i=1}^{k}) \vdash \sum_{i=0}^{k} (\Gamma_{0i} + \sum_{j \in I_i} \Gamma_{j}) \vdash (P\{N/x\})(Q\{N/x\}) : \alpha$. Clearly $\sum_{i=0}^{k} \Gamma_{0i} = \sum_{i=1}^{n} \sum_{j \in I_i} \Gamma_{j} = \sum_{i=1}^{n} \Gamma_{i} = \sum_{i=0}^{n} \Gamma_{i}$ and $(P\{N/x\})(Q\{N/x\}) = (PQ)\{N/x\}$. Moreover we get that $\#app(\pi) = 1 + \sum_{i=0}^{n} \#app(\pi'_i) = 1 + \sum_{i=0}^{k} \#app(\pi_{0i}) + \sum_{j \in I_i} \#app(\pi_{j}) = (1 + \sum_{i=0}^{k} \#app(\pi_{0i})) + \sum_{i=0}^{n} \sum_{j \in I_i} \#app(\pi_{j}) = \#app(\pi_0) + \sum_{i=1}^{n} \#app(\pi_{i}) = \sum_{i=0}^{n} \#app(\pi)$, which concludes the proof.

From this, it follows that the number of rules $\text{app}$ in the derivation of a $\beta$-redex, decrements in a derivation of its contractum.

**Corollary 4.12.** Let $M, N \in \Lambda_\perp$. If $\pi \vdash \Gamma \vdash (\lambda x.M)N : \alpha$ there exists a derivation $\pi'$ such that $\pi' \vdash \Gamma \vdash M\{N/x\} : \alpha$ with $\#app(\pi') = \#app(\pi) - 1$.

**Proof.** The derivation $\pi$ has the form

$$\pi_0 \vdash \Gamma_0, x : [\beta_1, \ldots, \beta_n] \vdash M : \alpha \quad \text{lam} \quad \pi_i \vdash \Gamma_i : \beta_i \text{ for } 1 \leq i \leq n$$

$$\sum_{i=0}^{n} \Gamma_i \vdash (\lambda x.M)N : \alpha$$

where $n \in \mathbb{N}$ and $\Gamma = \sum_{i=0}^{n} \Gamma_i$. By Lemma 4.11 there exists $\pi'_0 \vdash \sum_{i=0}^{n} \Gamma_i \vdash M\{N/x\} : \alpha$ such that $\#app(\pi') = \sum_{i=0}^{n} \#app(\pi_i) = \#app(\pi) - 1$.

From Corollary 4.12 it follows that the number of $\text{app}$ decreases exactly by 1 at each step of head reduction. So $\#app(\pi)$ provides an upper bound for the number of steps necessary to get the principal hnf of a solvable term, as observed by de Carvalho in [30].

**Lemma 4.13.** If $\pi \vdash \Gamma \vdash M : \alpha$ then the head reduction of $M$ has length at most $\#app(\pi)$.

Unfortunately, the measure $\#app(\pi)$ is not enough for proving the approximation theorem. The reason is that, in order to compute the Böhm tree of a $\lambda$-term $M$, one needs to
reduce also redexes that are not in head-position. E.g., consider the following derivation \( \pi \):

\[
\begin{align*}
  x : [\omega \to \alpha] &\vdash x : \omega \to \alpha \\
  x : [\omega \to \alpha] &\vdash (I y) : \alpha \\
\end{align*}
\]

When reducing \( x(I y) \to_{\beta} xy \), the only possible derivation \( \pi' \) of \( x : [\omega \to \alpha] \vdash xy : \alpha \) is:

\[
\begin{align*}
  x : [\omega \to \alpha] &\vdash x : \omega \to \alpha \\
  x : [\omega \to \alpha] &\vdash xy : \alpha \\
\end{align*}
\]

The number of \( \text{app} \) has not decreased in this case, so we cannot use \#app(\(-\)) as a decreasing measure in the proof of the left-to-right implication of Theorem 4.16. We can however find an approximant \( t \in \text{BT}^*(x(I y)) \) with that typing by realizing that in \( \pi \) the subterm \( I y \) is basically used as the approximant \( \bot \). This is the key idea behind the next lemma.

Given \( M \in \Lambda_{\bot} \) and a redex occurrence \( R = (\lambda x.P)Q \) in \( M \), say \( M = C[R] \) for some single hole \( \lambda \)-context \( C[-] \), we denote by \( M \|_{\bot/R} \) the \( \lambda \)-\( \bot \)-term \( C[\bot] \). Moreover, we write \( M \to_{\beta} M' \) to indicate that the contracted \( \beta \)-redex is \( R \), namely that \( M' = C[P/Q/x] \).

**Lemma 4.14** (Weighted Subject Reduction). Let \( M, M' \in \Lambda_{\bot} \) be such that \( M \to_{\beta} M' \). If \( \pi \gg \Gamma \vdash M : \alpha \), then there is \( \pi' \gg \Gamma \vdash M' : \alpha \) such that one of the following cases holds:

1. \( \#\text{app}(\pi') < \#\text{app}(\pi) \),
2. \( \pi' \simeq \pi \) and there exists \( \pi'' \gg \Gamma \vdash M \|_{\bot/R} : \alpha \) such that \( \pi'' \simeq \pi \).

**Proof.** Let \( M = C[R] \) for a single hole \( \lambda \)-context \( C[-] \). We proceed by induction on \( C[-] \).

**Case** \( [-] \). We have \( M = \overline{R} = (\lambda x.P)Q \) and \( M' = P/Q/x \). The thesis is then given by Corollary 4.12. More precisely, we are in case (i).

**Case** \( P(C[-]) \). We have \( M = P(C[R]) \) and \( M' = P(C[R']) \) where \( R \to_{\beta} R' \). Then, the derivation \( \pi \) has the form

\[
\pi_0 \gg \Gamma_0 \vdash P : [\beta_1, \ldots, \beta_n] \to \alpha \quad \pi_i \gg \Gamma_i \vdash C[R] : \beta_i \quad \text{for } 1 \leq i \leq n
\]

where \( n \in \mathbb{N} \) and \( \Gamma = \sum_{i=0}^{n} \Gamma_i \).

For all \( 1 \leq i \leq n \) by induction hypothesis there is \( \pi'_i \gg \Gamma_i \vdash C[R'] : \beta_i \) such that either

\[
\#\text{app}(\pi'_i) < \#\text{app}(\pi_i),
\]

or

\[
\pi'_i \simeq \pi_i \simeq \pi''_i \gg \Gamma_i \vdash C[\bot] : \beta_i.
\]

In this case we take \( \pi' = \text{App}(\pi_0, \{\pi'_i\}_{i=1}^{n}) \).

If every \( i \) satisfies (4.4) then \( \pi' \simeq \pi \). By taking \( \pi'' = \text{App}(\pi_0, \{\pi''_i\}_{i=1}^{n}) \) we obtain the case (ii) of the thesis. Notice that the eventuality \( n = 0 \) falls in this case.

If there is an \( i \) that satisfies (4.3) then \#app(\pi') < #app(\pi), so the case (i) is proved.

**Case** \( (C[-])P \). We have \( M = (C[R])P \) and \( M' = (C[R'])P \) where \( R \to_{\beta} R' \). Then, the derivation \( \pi \) has the form

\[
\pi_0 \gg \Gamma_0 \vdash C[R] : [\beta_1, \ldots, \beta_n] \to \alpha \quad \pi_i \gg \Gamma_i \vdash P : \beta_i \quad \text{for } 1 \leq i \leq n
\]

where \( n \in \mathbb{N} \) and \( \Gamma = \sum_{i=0}^{n} \Gamma_i \). By induction hypothesis there exists a derivation \( \pi'_0 \gg \Gamma_0 \vdash C[R'] : [\beta_1, \ldots, \beta_n] \to \alpha \) such that either \#app(\pi'_0) < #app(\pi_0), or \( \pi'_0 \simeq \pi_0 \simeq \pi''_0 \) for some \( \pi''_0 \gg \Gamma_0 \vdash C[\bot] : [\beta_1, \ldots, \beta_n] \to \alpha \). In the former case, the thesis is proved taking \( \pi' = \text{App}(\pi'_0, \{\pi'_i\}_{i=1}^{n}) \) and in the latter also \( \pi'' = \text{App}(\pi''_0, \{\pi''_i\}_{i=1}^{n}) \).
Case \( \lambda x.C[-] \). We have \( M = \lambda x.C[R] \) and \( M' = \lambda x.C[R'] \), where \( R \rightarrow R' \). Then \( \pi \) has the form

\[
\pi_0 \triangleright \Gamma, x : [\beta_1, \ldots, \beta_n] \vdash C[R] : \beta \\
\Gamma \vdash \lambda x.C[R] : [\beta_1, \ldots, \beta_n] \rightarrow \beta
\]

for \( [\beta_1, \ldots, \beta_n] \rightarrow \beta = \alpha \). By induction hypothesis there is \( \pi_0' \triangleright \Gamma, x : [\beta_1, \ldots, \beta_n] \vdash C[R_] : \beta \) such that either \( \#\text{app}(\pi_0') < \#\text{app}(\pi_0) \), or \( \pi_0' \simeq \pi_0 \simeq \pi_0'' \) for some \( \pi_0'' \triangleright \Gamma, x : [\beta_1, \ldots, \beta_n] \vdash C[\bot] : \beta \). In the former case, the thesis is proved by taking \( \pi' = \text{Lam}(x, \pi_0') \), and in the latter also \( \pi'' = \text{Lam}(x, \pi_0'') \).

As a note aside, Lemma 4.14 gives in particular the subject reduction property. The subject expansion can be proved equally easily, as done in [78, §2.4]. These two properties provide yet another soundness proof for relational graph models.

4.5. The Approximation Theorem. We show that all relational graph models satisfy the Approximation Theorem stating that the interpretation of a \( \lambda \)-term is given by the union of the interpretations of its finite approximants (Theorem 4.16). As mentioned in the introduction, we provide a new combinatorial proof that does not exploits reducibility candidates nor Ehrhard’s notion of Taylor expansion. Actually, it is an easy consequence of our Weighted Subject Reduction (Lemma 4.14).

From the Approximation Theorem, we get that the \( \lambda \)-theory induced by any relational graph model \( D \) includes \( B \) (Corollary 4.17) and, if \( D \) is extensional, also \( H^+ \) (Corollary 4.18).

Lemma 4.15. Let \( M \in \Lambda_{\bot} \). If \( M \) is in \( \beta \)-normal form and \( \Gamma \vdash M : \alpha \) then \( \Gamma \vdash \text{da}(M) : \alpha \).

Proof. By a straightforward induction on \( M \).

Notice that the hypothesis that \( M \) is in \( \beta \)-normal form is necessary to prove Lemma 4.15. Indeed, for \( M = Ix \) we have \( x : [\alpha] \vdash M : \alpha \), whereas \( \text{da}(M) = \bot \) cannot be typed.

Given \( M \in \Lambda_{\bot} \) we denote by \( \#\text{red}_{\beta}(M) \) the number of occurrences of \( \beta \)-redexes in \( M \).

Theorem 4.16 (Approximation Theorem). Let \( M \in \Lambda_{\bot} \). Then \( \langle \Gamma, \alpha \rangle \in [M] \) if and only if there exists \( t \in \text{BT}^+(M) \) such that \( \langle \Gamma, \alpha \rangle \in [t] \). Therefore \( [M] = \bigcup_{t \in \text{BT}^+(M)} [t] \).

Proof. (\( \Rightarrow \)) Let \( \pi \triangleright \Gamma \vdash M : \alpha \). We proceed by induction on the pair \( (\#\text{app}(\pi), \#\text{red}_{\beta}(M)) \) lexicographically ordered.

Case \( \#\text{red}_{\beta}(M) = 0 \). By Lemma 4.15 \( \Gamma \vdash \text{da}(M) : \alpha \) and clearly \( \text{da}(M) \in \text{BT}^+(M) \).

Case \( \#\text{red}_{\beta}(M) > 0 \). Let \( R \) be any occurrence of a \( \beta \)-redex in \( M \) and \( M \rightarrow R M' \). By Lemma 4.14 there is a derivation \( \pi' \triangleright \Gamma \vdash M' : \alpha \) such that either (i) \( \#\text{app}(\pi') < \#\text{app}(\pi), \) or (ii) there exists \( \pi'' \triangleright \Gamma \vdash M\{\bot/R\} : \alpha \) such that \( \pi'' \simeq \pi \).

In Case (i) we apply the induction hypothesis to \( \pi' \) and get \( t \in \text{BT}^+(M') = \text{BT}^+(M) \) such that \( \Gamma \vdash t : \alpha \).

In Case (ii) we can apply the induction hypothesis to \( \pi'' \), as \( \pi'' \simeq \pi \) implies \( \#\text{app}(\pi'') = \#\text{app}(\pi), \) and moreover \( \#\text{red}_{\beta}(M\{\bot/R\}) < \#\text{red}_{\beta}(M) \). We get \( t \in \text{BT}^+(M\{\bot/R\}) \) such that \( \Gamma \vdash t : \alpha \). Since moreover \( \text{BT}^+(M\{\bot/R\}) \subseteq \text{BT}^+(M) \) by Lemma 1.16, we are done.

(\( \Leftarrow \)) We proceed by induction on \( t \). The case \( t = \bot \) is vacuous, as \( \bot \) is not typable. So let \( t = \lambda x_1 \ldots x_n.xt_1 \cdots t_m \) where \( n, m \in \mathbb{N} \). We suppose that the variable \( x \) is bound, the
other case being analogous. The given derivation tree of $\Gamma \vdash t : \alpha$ must have the form\(^6\)

\[
\Delta \vdash x : b_1 \to \cdots \to b_m \to \beta \quad \Gamma_{ij}, x_1 : a^{ij}_1, \ldots, x_n : a^{ij}_n \vdash t_i : \beta_{ij} \quad \text{for all } i, j
\]

\[
\Delta + \sum_{i=1}^m \sum_{j=1}^{k_i} \Gamma_{ij}, x_1 : \sum_{i=1}^m \sum_{j=1}^{k_i} a^{ij}_1, \ldots, x_n : \sum_{i=1}^m \sum_{j=1}^{k_i} a^{ij}_n \vdash t_1 \cdots t_m : \beta
\]

where for all \(i \leq m\) we have \(b_i = [\beta_{1i}, \ldots, \beta_{ki}]\) for some \(k_i \in \mathbb{N}\); \(\Delta = x : b_1 \to \cdots \to b_m \to \beta\);

\(\Gamma = \Delta + \sum_{i=1}^m \sum_{j=1}^{k_i} \Gamma_{ij}; a^j = \sum_{i=1}^m \sum_{j=1}^{k_i} a^{ij}_\ell\) for all \(\ell \leq n\); finally, \(\alpha = a_1 \to \cdots \to a_n \to \beta\).

As \(t \in \text{BT}^e(M)\) we have that \(t = e(N)\) for some \(N =_\beta M\). By Definition 1.15, we have \(N = \lambda x_1 \cdots x_n. x N_1 \cdots N_m\) with \(t_i = e(N_i)\) for all \(i \leq m\). By induction hypothesis we get \(\Gamma_{ij}, x_1 : a^{ij}_1, \ldots, x_n : a^{ij}_n \vdash N_i : \beta_{ij}\) for all \(i, j\). By replacing each \(t_i\) by \(N_i\) in the proof tree above, we get a derivation of \(\Gamma \vdash N : \alpha\). Since \(N =_\beta M\), by soundness we get \(\Gamma \vdash M : \alpha\). \(\square\)

The following result first appeared in print in [67], but was already known in the folklore (see the discussion in [23]). Notice that it is stronger than Theorem 6 in [72] which only shows that the \(\lambda\)-theories induced by strongly linear relational models are sensible.

**Corollary 4.17.** For all rgm’s \(\mathcal{D}\) we have that \(\mathcal{B} \subseteq \text{Th}(\mathcal{D})\). In particular \(\text{Th}(\mathcal{D})\) is sensible and \([M]^\mathcal{D} = \emptyset\) for all unsolvable \(\lambda\)-terms \(M\).

**Proof.** From Theorem 4.16 we get \([M] = [\text{BT}(M)] = \bigcup_{t \in \text{BT}^*(M)} [t]\). Therefore, whenever \(\text{BT}(M) = \text{BT}(N)\) we have \([M] = [\text{BT}(M)] = [\text{BT}(N)] = [N]\). Thus \(\mathcal{B} \subseteq \text{Th}(\mathcal{D})\). \(\square\)

In the next corollary we are going to use the Lévy’s characterization of Morris’s inequational theory \(\subseteq_{\mathcal{H}^+}\) in terms of extensional approximants (Theorem 2.17). The extensional approximants of a \(\lambda\)-term \(M\) are interpreted as usual by setting \([\text{BT}^e(M)] = \bigcup_{t \in \text{BT}^e(M)} [t]\).

**Corollary 4.18.** For an rgm \(\mathcal{D}\), the following are equivalent:

(i) \(\mathcal{D}\) is extensional,

(ii) \(\subseteq_{\mathcal{H}^+} \subseteq \text{Th}_{\subseteq}(\mathcal{D})\),

(iii) \(\mathcal{H}^+ \subseteq \text{Th}(\mathcal{D})\).

**Proof.** (i \(\Rightarrow \) ii) From Theorem 4.16 we obtain \([M] = \bigcup_{t \in \text{BT}^*(M)} [t]\). From the extensionality of \(\mathcal{D}\), we get \([M] = \bigcup_{M' \rightarrow_M M, t \in \text{BT}^*(M')} [t] = \bigcup_{M' \rightarrow_M M, t \in \text{BT}^*(M')} [\text{nf}_e(t)] = [\text{BT}^e(M)]\). So, we have that \(\text{BT}^e(M) \subseteq \text{BT}^e(N)\) entails \([M] = [\text{BT}^e(M)] \subseteq [\text{BT}^e(N)] = [N]\).

(ii \(\Rightarrow \) iii) Trivial.

(iii \(\Rightarrow \) i) By Lemma 3.17. \(\square\)

5. **The Minimal Relational Graph Theory**

In this section we show that a minimal inequational graph theory exists, and that it is exactly the inequational theory induced by the model \(\mathcal{E}\) defined in Example 3.10.

\(^6\) The “double line” in the derivation tree is a shortcut to indicate the simultaneous application of zero, one, or many rules of the same kind.
5.1. The Minimal Inequational Graph Theory. We start by defining an inequational theory $\sqsubseteq_r$ and prove that it is included in $\text{Th}_{\sqsubseteq}(\mathcal{D})$ for every relational graph model $\mathcal{D}$.

**Definition 5.1.** Given $M, N \in \Lambda$, we let $M \sqsubseteq_r N$ whenever there exists a Böhm-like tree $U$ such that $\text{BT}(M) \leq_\perp U \geq^\omega_0 \text{BT}(N)$.

The fact that this definition involves $\eta$-expansions and that $\sqsubseteq_r \subseteq \text{Th}_{\sqsubseteq}(\mathcal{D})$ holds also for non-extensional relational graph models should not be surprising. Indeed, when considering the original graph model $\mathcal{P}_\omega$ defined by Plotkin [74] and Scott [82] the situation is actually analogous (but symmetrical), and no graph model is extensional.

**Example 5.2.**
(1) $J \sqsubseteq_r I$ while $I \not\sqsubseteq_r J$.
(2) Let $(M_n)_{n \in \mathbb{N}}$ be the effective sequence defined by $M_n = J$ if $n$ is even and $M_n = \Omega$ otherwise. Then we have $[M_n]_{n \in \mathbb{N}} \sqsubseteq_r [I]_{n \in \mathbb{N}}$.

It follows from [76] that $M \sqsubseteq_r N \sqsubseteq_r M$ if and only if $\mathcal{B} \vdash M = N$. The inequational theory $\sqsubseteq_r$ admits the following characterization in terms of Böhm tree approximants.

**Lemma 5.3.** Let $M, N \in \Lambda$. We have $M \sqsubseteq_r N$ if and only if for all $t \in \text{BT}^*(M)$ there exists $s \in \text{BT}^*(N)$ such that $t \leq_\perp u \rightarrow^\eta s$ for some $u \in \text{NF}_{\beta\perp}$.

**Proof.** ($\Rightarrow$) By structural induction on $t$. If $t = \perp$, then we can take $s = u = \text{da}(M)$.

Otherwise $t \neq \perp$ entails that $M$ has an hnf $M = \beta \, \lambda \vec{x} \, z_1 \ldots z_m \, x_i M_1 \cdots M_k \, P_1 \cdots P_m$. By Definition 5.1, there is a Böhm-like tree $U = \lambda \vec{x} \, z_1 \ldots z_m \, x_i U_1 \cdots U_k V_1 \cdots V_m$ such that $\text{BT}(M_j) \leq_\perp U_j$ and $\text{BT}(P_i) \leq_\perp V_i \geq^\omega_0 z_t$, and $N = \beta \, \lambda \vec{x} \, x_i N_1 \cdots N_k$ with $U_j \leq^\omega_0 \text{BT}(N_j)$. Thus, we have $t = \lambda \vec{x} \, z_1 \ldots z_m \, x_i t_1 \cdots t_k t'_1 \cdots t'_m$ for $t_j \in \text{BT}^*(M_j)$ and $t'_\ell \in \text{BT}^*(P_i)$. Since for all $j \leq k$ we have $M_j \sqsubseteq_r N_j$ and for all $\ell \leq m$ we have $P_\ell \sqsubseteq_r z_t$, we can apply the induction hypothesis and get $t_j \leq_\perp u_j \rightarrow^\eta s_j$ for some $s_j \in \text{BT}^*(N_j)$ and $t'_\ell \leq_\perp u'_\ell \rightarrow^\eta z_\ell$. As a consequence $t \leq_\perp \lambda \vec{x} \, z_1 \ldots z_m \, x_i u_1 \cdots u_k u'_1 \cdots u'_m \rightarrow^\eta \lambda \vec{x} \, x_i s_1 \cdots s_k \in \text{BT}^*(N)$.

($\Leftarrow$) We prove $M \sqsubseteq_r N$ coinductively. If $M$ is unsolvable, then we are done.

Otherwise there is $t \in \text{BT}^*(M)$ of the form $t = \lambda \vec{x} \, z_1 \ldots z_m \, x_i t_1 \cdots t_k t'_1 \cdots t'_m$ and $s = \lambda \vec{x} \, x_i s_1 \cdots s_k \in \text{BT}^*(N)$ such that $t \leq_\perp \lambda \vec{x} \, z_1 \ldots z_m \, x_i t_1 \cdots t_k t'_1 \cdots t'_m \rightarrow^\eta s$. This entails that $M = \beta \, \lambda \vec{x} \, z_1 \ldots z_m \, x_i M_1 \cdots M_k \, P_1 \cdots P_m$ and $N = \beta \, \lambda \vec{x} \, x_i N_1 \cdots N_k$ with $t_j \in \text{BT}^*(M_j)$, $s_j \in \text{BT}^*(N_j)$ for all $j \leq k$, $z_\ell \notin \text{FV}(\text{BT}(x_i \check{M} \check{N}))$, and $t'_\ell \in \text{BT}^*(P_i)$ for all $\ell \leq m$. By coinductive hypothesis $M_j \sqsubseteq_r N_j$, i.e., there are Böhm-like trees $U_j$ such that $\text{BT}(M_j) \leq_\perp U_j \geq^\omega_0 \text{BT}(N_j)$. Since for all $t'_\ell \in \text{BT}^*(P_i)$ there is an $\eta$-expansion $u'_\ell$ of $z_\ell$ such that $t'_\ell \leq_\perp u'_\ell$, then there exists a Böhm-like tree $V_\ell$ such that $\text{BT}(P_i) \leq_\perp V_\ell \geq^\omega_0 z_\ell$. As a consequence $\text{BT}(M) \leq_\perp \lambda \vec{x} \, x_i U_1 \cdots U_k V_1 \cdots V_m \geq^\omega_0 \text{BT}(N)$, which shows $M \sqsubseteq_r N$.

**Proposition 5.4.** Let $M, N \in \Lambda$. If $M \sqsubseteq_r N$ then $\mathcal{D} \models M \sqsubseteq N$ for every rgm $\mathcal{D}$.

**Proof.** By Lemma 5.3 for all $t \in \text{BT}^*(M)$ there are $s \in \text{BT}^*(N)$ and $u \in \text{NF}_{\beta\perp}$ such that $t \leq_\perp u \rightarrow^\eta s$. Since $t \leq_\perp u$ we get $t \in \text{BT}^*(u)$ and, by Theorem 4.16, we obtain $[t] \subseteq [u]$. From Lemma 3.17(i) and Corollary 4.9 we have that $[u] \subseteq [s]$ holds. It follows that $[\text{BT}(M)] \subseteq [\text{BT}(N)]$, so we conclude by applying Theorem 4.16.

We now show that $\sqsubseteq_r$ is representable by some relational graph model.

---

7 I.e. $\mathcal{P}_\omega \models M \sqsubseteq N$ exactly when there is a Böhm-like tree $U$ such that $\text{BT}(M) \leq^\omega_0 U \leq_\perp \text{BT}(N)$ [47].
5.2. The Model $\mathcal{E}$ Induces Minimal Theories. Let $\mathcal{E} = (E, i) = (\mathbb{N}, \emptyset)$ be the relational graph model defined in Example 3.10. This model has infinitely many atoms, that we denote by $(\xi_n)_{n \in \mathbb{N}}$, and as injection $i : M_T(E) \times E \to E$ simply the inclusion, therefore no atom $\xi_n$ can be equal to an arrow $a \to \alpha$. In other words, the elements $\alpha \in E$ are generated by:

$$\alpha := \xi_n \mid a \to \alpha \quad a := [\alpha_1, \ldots, \alpha_k] \quad (\text{for } n, k \geq 0).$$

Recall that we provided the type inference rules in Figure 4. We are going to show that the interpretations of two $\lambda$-terms $M$ and $N$ are different whenever $M \not\succeq_N N$.

Notice that every element $\alpha \in E$ can be written uniquely as $\alpha = a_1 \to \cdots \to a_n \to \xi_i$. In this case, the atom $\xi_i$ is called the range of $\alpha$ and denoted by $\text{rg}(\alpha)$. We use the compact notion $\omega^k \to \alpha$ to denote the element $\omega \to \cdots \to \omega \to \alpha$ (with $k$ occurrences of $\omega$).

Recall that the size $\#t$ of $t \in \text{NF}_{\beta \perp}$ has been introduced in Definition 1.14.

**Lemma 5.5.** Let $M, N \in \Lambda$. If $M \not\succeq_{\mathcal{H}^*} N$ but $M \not\succeq_N N$, then there are $\Gamma, \alpha$ such that:

(i) $\Gamma \vdash_E t : \alpha$ for some $t \in \text{BT}^*(M)$,

(ii) for all $u \in \text{BT}^*(N)$ we have $\Gamma \not\models_E u : \alpha$,

(iii) $\text{rg}(\alpha) = \xi_{\#t}$,

(iv) for all $\beta \in \Gamma$, $\text{rg}(\beta) = \xi_j$ for some $j \leq \#t$.

**Proof.** Since $M \not\succeq_N N$, we have that $M$ must be solvable. As moreover $M \not\succeq_{\mathcal{H}^*} N$, by Remark 2.7 we get that $M, N$ have similar hnf’s. Therefore, only two cases are possible.

1) $M =_\beta \lambda x_1 \ldots x_n x_1 M_1 \cdots M_k$ and $N =_\beta \lambda x_1 \ldots x_m x_1 N_1 \cdots N_k P_1 \cdots P_m$ for $m > 0$.

We suppose that $x_i$ is free, the other case being analogue. This case follows easily by taking $t = \lambda \overline{x} x_i \perp \cdots \perp \in \text{BT}^*(M)$ whose size is $n + 1$, $\Gamma = x_i : [\omega^k \to \xi_{n+1}]$ and $\alpha = \omega^n \to \xi_{n+1}$.

The fact that $\Gamma \not\models_E u : \alpha$ for all $u = \lambda \overline{x} x_i u_1 \cdots u_{k+m} \in \text{BT}^*(N)$ follows from $m > 0$ and the fact that $\xi_{n+1}$ is an atom, hence different from any arrow type by definition of $\mathcal{E}$.

2) $M =_\beta \lambda x_1 \ldots x_n z_1 \ldots z_m x_1 M_1 \cdots M_k$ and $N =_\beta \lambda \overline{x} x_i N_1 \cdots N_k$ where, for every $\ell \leq m$ there is a Böhm-like tree $V$ such that $\text{BT}(P) \leq_1 V \geq_\ell z_\ell$, for every $j \leq k$ we have $M_j \not\succeq_{\mathcal{H}^*} N_j$ but $M_j \not\succeq_N N_j$ for some $q$. We suppose that $x_i$ is free, the other case being analogue. By induction hypothesis, there is $t_q \in \text{BT}^*(M_q)$ such that $\Gamma \vdash t_q : \alpha$ with $\text{rg}(\alpha) = \xi_{\#t_q}$, for all $\beta \in \Gamma$ we have $\text{rg}(\beta) = \xi_j$ for some $j \leq \#t_q$ and for all $u \in \text{BT}^*(N_q)$ we have $\Gamma \not\models_E u : \alpha$. On the one side, we construct the derivation:

$$\begin{array}{c}
\Gamma_0 \vdash x_i : \omega^{q-1} \to [\alpha] \to \omega^{k+m-q} \to \xi_{\#t} \\
\Gamma_0 + \Gamma \vdash x_i t_1 \cdots t_k s_1 \cdots s_m : \xi_{\#t}
\end{array}$$

where $\Gamma_0 = x_i : [\omega^{q-1} \to [\alpha] \to \omega^{m+k-q} \to \xi_{\#t}]$, $\Gamma = \Gamma_0 + (x_1 : a_1, \ldots, x_n : a_n)$, for all $j \leq k$ we have $t_j \in \text{BT}^*(M_j)$, and for all $\ell \leq m$ we have $s_\ell \in \text{BT}^*(P)$. On the other side, each $u \in \text{BT}^*(N) - \{\perp\}$ must have the shape $u = \lambda \overline{x} x_i u_1 \cdots u_k$ and each derivation of $\Gamma_0 + \Gamma_1 \vdash u : \xi_{\#t}$ requires to derive $\Gamma \vdash u_q : \alpha$.

Indeed, since all $\beta \in \Gamma$ satisfy $\text{rg}(\beta) \leq \#t_q < \#t$, they cannot be used to produce a $\xi_{\#t}$ so the decomposition $\Gamma_0 + \Gamma$ is in fact unique:

$$\begin{array}{c}
\Gamma_0 \vdash x_i : \omega^{q-1} \to [\alpha] \to \omega^{m+k-q} \to \xi_{\#t} \\
\Gamma_0 + \Gamma \vdash x_i u_1 \cdots u_k : \omega^m \to \xi_{\#t}
\end{array}$$

By induction hypothesis $\Gamma \not\models_E u : \alpha$ is impossible, which entails $\Gamma_0 + \Gamma_1 \not\models_E u : a_1 \to \cdots \to a_n \to \omega^m \to \xi_{\#t}$.

\[\square\]
We are now able to show that $E$ induces the same $\lambda$-theory as Engeler's model [39] and the same inequational theory as the filter model defined by Ronchi Della Rocca in [76].

**Theorem 5.6.** For $M, N \in \Lambda$ we have

$$M \subseteq_r N \iff E \models M \subseteq N$$

Therefore $Th_r(E) = \subseteq_r$ and $Th(E) = B$.

**Proof.** ($\Rightarrow$) It follows immediately by Proposition 5.4.

($\Leftarrow$) Suppose, by the way of contradiction, that $M \not\subseteq_r N$ but $E \models M \subseteq N$. Since $Th_r(E)$ is sensible, Lemma 2.3 entails $M \subseteq_r N$. By Lemma 5.5, there exists $t \in BT^*(M)$ and $\Gamma, \alpha$ such that $\Gamma \vdash t : \alpha$ while $\Gamma \not\models u : \alpha$ for all $u \in BT^*(N)$. By the Approximation Theorem, we have $(\Gamma, \alpha) \in [M] - [N]$, which is impossible.

The above proof-technique could be suitably generalized to prove that all non-extensional relational graph models induce the same inequational theory, namely $\subseteq_r$.

**Theorem 5.7.** The relation $\subseteq_r$ is the minimal inequational graph theory. Similarly, $B$ is the minimal relational graph theory.

### 5.3. A Semantic Characterization of Normalizability

We now show that in the model $E$ $\beta$-normalizable $\lambda$-terms have a simple semantic characterization. Indeed, since there are no equations between atoms and arrow types, it makes sense to define whether $\omega$ occurs in a type $\alpha$ with a certain polarity $p \in \{+, -\}$.

**Definition 5.8.** For all elements $\alpha$ of $E$ the relations $\omega \in^+ \alpha$ and $\omega \in^- \alpha$ are defined by mutual induction as follows (where $p$ is a polarity and $\neg p$ denotes the opposite polarity):

(i) $\omega \in^- a \rightarrow \beta$ if $a = \omega$;
(ii) if $\omega \in^p \beta$ then $\omega \in^p a \rightarrow \beta$;
(iii) if $\omega \in^- p \beta$ then $\omega \in^- (\beta + a) \rightarrow \gamma$.

When $\omega \in^+ \alpha$ (resp. $\omega \in^- \alpha$) holds we say that $\omega$ occurs positively (resp. negatively) in $\alpha$.

We write $\omega \notin^p \alpha$ whenever $\omega$ does not occur in $\alpha$ with polarity $p$.

These notions extend to multisets in the obvious way, that is, $\omega \in^p [\alpha_1, \ldots, \alpha_n]$ whenever $\omega \in^p \alpha_i$ for some index $i$. Similarly, $\omega \in^p \Gamma$ whenever there is $x \in \text{Var}$ such that $\omega \in^p \Gamma(x)$.

**Theorem 5.9.** Let $M \in \Lambda$. The following are equivalent:

1. $M$ has a $\beta$-normal form,
2. $\Gamma \vdash E : \alpha$ for some environment $\Gamma$ and type $\alpha$ such that $\omega \notin^+ \alpha$ and $\omega \notin^- \Gamma$.

**Proof.** ($1 \Rightarrow 2$) Straightforward induction on the derivation of $\Gamma \vdash nf_\beta(M) : \alpha$.

($2 \Rightarrow 1$) We proceed by structural induction on the pair $(\Gamma, \alpha)$. By Lemma 4.13, $M$ has a head normal form $\lambda x_1 \ldots x_n . x_1 M_1 \cdots M_k$ having type $\alpha$ in the context $\Gamma$, which entails $\alpha = a_1 \rightarrow \cdots \rightarrow a_n \rightarrow \alpha'$. So, there exists a derivation of the form:

\[
\begin{array}{c}
\Gamma_0 \vdash x_i : b_1 \rightarrow \cdots \rightarrow b_k \rightarrow \alpha' \\
\Gamma, x_1 : a_1, \ldots, x_n : a_n \vdash x_i M_1 \cdots M_k : \alpha' \\
\end{array}
\]

\[
\frac{\text{app}}{\Gamma, x_1 : a_1, \ldots, x_n : a_n \vdash x_i M_1 \cdots M_k : \alpha'}
\]

where $\Gamma_0 = [x_i : b_1 \rightarrow \cdots \rightarrow b_k \rightarrow \alpha']$, for all $j \leq k$ we have $b_j = [\beta_{j1}, \ldots, \beta_{jk}]$ and $\Gamma, x_1 : a_1, \ldots, x_n : a_n = \Gamma_0 + \sum_{j=1}^k \sum_{i=1}^{\ell_j} \Gamma j_\ell$. Since $\omega \notin^+ \alpha$ and $\omega \notin^- \Gamma$ we get for each
that \( b_j \) is non-empty, and moreover that \( \omega \notin \beta^+ \Gamma_{j\ell} \) and \( \omega \notin \Gamma^\ell \) for all \( \ell \leq k_j \). From the induction hypothesis, we get that all the \( M_i \)'s have a \( \beta \)-normal form.

As proved in [67], Theorem 5.9 holds for every relational graph model \( D \) preserving \( \omega \)-polarities (in a technical sense). An analogue of this theorem also holds for the usual intersection type systems [8]. However, for an extensional relational graph model \( D \) this lemma is enough to conclude \( \text{Th}_{\subseteq}(D) = \subseteq_{\mathcal{H}^+} \), while this is not the case for filter models. In other words, being extensional and preserving \( \omega \)-polarities are sufficient conditions for a relational graph model to be fully abstract for \( \mathcal{H}^+ \). We will now provide conditions that are both necessary and sufficient.

6. Characterizing Fully Abstract Relational Models of \( \mathcal{H}^+ \)

In this section we provide a characterization of those relational graph models that are (inequationally) fully abstract for \( \mathcal{H}^+ \). We first introduce the notion of \( \lambda \)-König relational graph model (Definition 6.5), and show that a relational graph model \( D \) is extensional and \( \lambda \)-König exactly when the induced inequational theory is the preorder \( \subseteq_{\mathcal{H}^+} \) (Theorem 6.8).

Since our proof technique does not rely on the quantitative properties of relational graph models, hereafter we rather prefer to use the categorical interpretation.

6.1. Lambda König Relational Graph Models.

Before entering into the technicalities we try to give the intuition behind our condition. The main issue is to find suitable conditions for assuring that if \( M, N \) have the same interpretation in a relational graph model \( D \) then \( M =_{\mathcal{H}^+} N \), equivalently that \( M \not=_{\mathcal{H}^+} N \) implies \( |M|_D \not= |N|_D \). Now, the idea behind Theorem 2.14 is that two \( \lambda \)-terms \( M, N \) are equal in \( \mathcal{H}^* \), but different in \( \mathcal{H}^+ \), when there is a (possibly virtual) position \( \sigma \in \mathbb{N}^{<\omega} \) such that, say, \( \text{BT}(M)_\sigma = x \) while \( \text{BT}(N)_\sigma \) is an infinite \( \eta \)-expansion of \( x \) following some \( T \in \mathcal{T}_\text{rec}^\infty \). As a consequence of this fact, our models need to separate \( x \) from any \( J^T_x \) for \( T \in \mathcal{T}_\text{rec}^\infty \) in order to be fully abstract for \( \mathcal{H}^+ \).

Notice now that in any extensional relational graph model \( D \), every element \( \alpha_0 \) is equal to an arrow, so one can always try to unfold \( \alpha \) following a function \( f \), starting with:

\[
\alpha_0 = a_0 \to \cdots \to a_{f(0)} \to \beta
\]

If there is an \( \alpha_1 \in a_{f(0)} \), then one can keep unfolding:

\[
\alpha_1 = a'_0 \to \cdots \to a'_{f(1)} \to \beta'
\]

and so on. More generally, at level \( \ell \) we have \( \alpha_\ell = b_0 \to \cdots \to b_{f(\ell)} \to \alpha' \) for some \( b_i \in M_f(D) \) and \( \alpha' \in D \) and as long as there exist an \( \alpha_{\ell+1} \in a_{f(\ell)} \), we can keep unfolding it at level \( \ell + 1 \). There are now two possibilities.

(1) If this process continues indefinitely, then we consider that \( \alpha \) can actually be unfolded following \( f \).

(2) Otherwise, if at some level \( \ell \) we have \( a_{f(\ell)} = \omega \), then the process is forced to stop and we consider that \( \alpha \) cannot be unfolded following \( f \).

\(^8\)Intuitively, a position \( \sigma \) is virtual if it does not belong to \( \text{BT}(M) \), but rather to one of its \( \eta \)-expansions. For more details we refer to [7, \S 10.3].
Now, as $T \in T^\infty_{\text{rec}}$ is a finitely branching infinite tree, by König’s lemma there exists an infinite path $f$ in $\text{BT}(J_T)$. Since the interpretation of $J_T$ is inductively defined (rather than coinductively), we will then have that $[\alpha] \to \alpha \notin |J_T|$ for any $\alpha$ whose unfolding can actually follow $f$.

In some sense such an $\alpha$ is witnessing within the model the existence of an infinite path $f$ in $T$, and therefore in $J_T$. The following is a formal definition of such a witness.

Recall from Definition 1.3, that $\Pi(T)$ denotes the set of infinite paths of a tree $T \in T^\infty$.

**Definition 6.1.** Let $D$ be an rgm, $T \in T^\infty_{\text{rec}}$ and $f \in \Pi(T)$.

- We coinductively define the set $W_{D,f}(T)$ of all witnesses for $T$ (in $D$) following $f$. An element $\alpha \in D$ belongs to $W_{D,f}(T)$ whenever there exist $a_0, \ldots, a_{f(0)} \in M_t(D)$ and $\alpha' \in D$ such that

  $$\alpha = a_0 \to \cdots \to a_{f(0)} \to \alpha'$$

  and there is a $\beta \in a_{f(0)}$ belonging to $W_{D,f_\geq 1}(T|_{f(0)})$ where $f_{\geq 1}$ maps $k \mapsto f(k+1)$.

- We say that $\alpha$ is a witness for $T$ in $D$ when there exists an $f \in \Pi(T)$ such that $\alpha$ is a witness for $T$ in $D$ following $f$.

- We let $W_D(T)$ be the set of all witnesses for $T$ in $D$.

We formalize the intuition given above by showing that $W_D(T)$ is constituted by those $\alpha \in D$ such that $[\alpha] \to \alpha \notin |J_T|$. We first prove the following technical lemmas.

**Lemma 6.2.** Let $D$ be an rgm. For all $T \in T^\infty_{\text{rec}}$ and $x \in \text{Var}$ we have $|J_T x|_x^D \subseteq |x|_x^D$.

**Proof.** Let $(a, \alpha) \in |J_T x|_x$. By Theorem 4.16 there is $t \in \text{BT}^*(J_T x)$ such that $(a, \alpha) \in |t|_x$. Proceeding by induction on $t$, we show that $a = [\alpha]$. The case $t = \bot$ is vacuous.

Consider $t = \lambda x_0 \ldots z_{T(e)} \cdot x_{t_0} \cdots x_{T(e)-1}$ where $t_i \in \text{BT}^*(J_T|_{i(z_i)})$. By Definition 3.11(ii) we have $(a, \alpha) \in |t|_x$ if and only if $\alpha = a_0 \to \cdots \to a_{T(e)-1} \to \alpha'$ for some $a_i \in M_t(D)$ and $\alpha' \in D$ such that $((a_0, \ldots, a_{T(e)-1}), \alpha') \in |x_{t_0} \cdots x_{T(e)-1}|_{x_0, \ldots, x_{T(e)-1}}$. By Definition 3.11(i) and (iii), we get $a = [b_0 \to \cdots \to b_{T(e)-1} \to \alpha']$ where $b_i = [\beta_{i,1}, \ldots, \beta_{i,k_i}]$ and there is a decomposition $a_i = \sum_{j=1}^{k_i} a_{i,j}$ such that $(a_{i,j}, \beta_{i,j}) \in |t_i|_{z_i}$. By the inductive hypothesis we have $a_{i,j} = [\beta_{i,j}]$. Therefore $a_i = [\beta_{i,1}, \ldots, \beta_{i,k_i}] = b_i$ which in its turn entails $a = [b_0 \to \cdots \to b_{T(e)-1} \to \alpha'] = [a_0 \to \cdots \to a_{T(e)-1} \to \alpha'] = [\alpha]$. \hfill $\Box$

**Lemma 6.3.** Let $D$ be an rgm. For all $T \in T^\infty_{\text{rec}}$, $\alpha \in W_D(T)$ and $t \in \text{BT}^*(J_T x)$ we have $([\alpha], \alpha) \notin |t|_x^D$.

**Proof.** We proceed by induction on the size $\#t$ of $t$.

**Case $\#t = 0$.** This case is trivial since $t = \bot$ and $|\bot|_x = \emptyset$.

**Case $\#t > 0$.** Then $t = \lambda x_0 \ldots z_{T(e)-1} \cdot x_{t_0} \cdots x_{T(e)-1}$ where each $t_i \in \text{BT}^*(J_T|_{i(z_i)})$ is such that $\#t_i < \#t$. By Definition 3.11(ii) we have $([\alpha], \alpha) \in |t_i|_x$ if and only if $\alpha = a_0 \to \cdots \to a_{T(e)-1} \to \alpha'$ for some $a_i = [\alpha_{i,1}, \ldots, \alpha_{i,k_i}]$ and $((\alpha], a_0, \ldots, a_{T(e)-1}, \alpha') \in |x_{t_0} \cdots x_{T(e)-1}|_{x_0, \ldots, x_{T(e)-1}}$. As $|t_i|_{z_i} \subseteq |z_i|_{z_i}$ by Lemma 6.2, we obtain $([\alpha_{i,j}], \alpha_{i,j}) \in |t_i|_{z_i}$ for all $i \leq T(e) - 1$ and $j \leq k_i$. Since $\alpha \in W_{D,f}(T)$ for some $f$, there exists a witness $\alpha_{f(0),j} \in a_{f(0)}$ for $T|_{f(0)}$ following $f_{\geq 1}$. By $\alpha_{f(0),j} \in W_D(T|_{f(0)})$ and the induction hypothesis we get $([\alpha_{f(0),j}], \alpha_{f(0),j}) \notin |t_f(0)|_{z_f(0)}$, which is a contradiction. \hfill $\Box$

By applying the Approximation Theorem we get the following characterization of $W_D(T)$.

**Proposition 6.4.** For any extensional rgm $D$ and any tree $T \in T^\infty_{\text{rec}}$,

$$W_D(T) = \{ \alpha \in D \mid ([\alpha], \alpha) \notin |J_T x|_x \}.$$
Proof. (⊆) Follows immediately from the Approximation Theorem 4.16 and from Lemma 6.3.

(⊇) Let α ∈ D such that ([α], α) /∈ J TF | α . We coinductively construct a path f such that α ∈ W f(T). As T is infinite we have J TX = β λz0 . . . zn.x(J T|α zn) and since D is extensional α = a0 → . . . → an → α′. From ([α], α) /∈ J TX | α and the soundness we get ([α], α) /∈ [λz0 . . . zn.x(J T|α zn)] | α . Therefore there exist an index k ≤ n such that αk /∈ ω and an element β ∈ ak such that ([β], β) /∈ J T|k zk | x . In particular, this entails that the subtree T |k is infinite because ([β], β) belongs to the interpretation of any finite η-expansion of zk. Therefore we set f(0) = k and, for all n ∈ N, f(n + 1) = g(n) where g is the function given by the coinductive hypothesis and satisfying β ∈ W D,g(T |k). By construction of f, we conclude that α ∈ W D,f(T).

It should be now clear that a relational graph model D, to be fully abstract for H +, needs for every λ-definable infinite η-expansion of the identity an element in D witnessing its infinite path, which exists by König’s lemma. This justifies the definition below.

Definition 6.5 (λ-König models). An rgm D is λ-König if for every T ∈ T rec, W D(T) ̸= ∅.

We will mainly focus on the λ-König condition, since the extensionality is clearly necessary, as λη ⊆ H +.

We start by showing that, if D is an extensional λ-König relational graph model, then Th ⊆ (D) = ⊆ H +. Indeed, since every T ∈ T rec has a non-empty set of witnesses W D(T), by Proposition 6.4, there is an element α ∈ W D(T) such that [α] → α /∈ |I| − |J T|. Thus, D separates I from all the J T’s for T ∈ T rec.

Theorem 6.6 (Inequational Full Abstraction). Let D be an extensional λ-König rgm, then:

\[ M \subseteq H^+ \iff D \models M \subseteq N \]

Proof. (⇒) This follows directly from Corollary 4.18.

(⇐) We assume, by the way of contradiction, that D \models M \subseteq N but M /⊆ H + N. By the maximality of \( \subseteq H^+ \) shown in Lemma 2.3 and the fact that \(|M|_x \subseteq |N|_x\) we must have M ⊆ H + N. By Theorem 2.14 there exists a context C[−] such that C[M] = Bη I and C[N] = Bη J T for some T ∈ T rec. By monotonicity of the interpretation |−| and since Bη ⊆ H + Th(D) by Corollary 4.18, we have |I| = |C[M]| ⊆ |C[N]| = |J T|. We derive a contradiction by applying Proposition 6.4.

We now show the converse, namely that if a relational graph model is (inequationally) fully abstract for H +, then it is extensional and λ-König.

Theorem 6.7. Let D be an rgm. If Th ⊆ (D) = ⊆ H + or Th(D) = H + then D is extensional and λ-König.

Proof. Obviously D must be extensional since H + is an extensional λ-theory. By contradiction, we suppose that it is not λ-König. Then there is T ∈ T rec such that W D(T) = ∅ and, by Proposition 6.4, we get |I| = |J T|. This is impossible since I /⊆ H + J T.

From Theorem 6.6 and Theorem 6.7 we get the main result of this section.

Theorem 6.8. For an rgm D, the following are equivalent:

(i) D is extensional and λ-König.
(ii) D is inequationally fully abstract for H +.
(iii) D is fully abstract for H +.
In particular, the model $\mathcal{D}_*$ induces the same inequational and $\lambda$-theories as Coppo, Dezani-Ciancaglini and Zacchì’s filter model [26], a result first appeared in [67].

**Corollary 6.9.** The model $\mathcal{D}_*$ of Example 3.10 is inequationally fully abstract for Morris’s preorder $\subseteq_\mathcal{H}^*$. In particular $\text{Th}(\mathcal{D}_*) = \mathcal{H}^*$.

7. **Characterizing Fully Abstract Relational Models of $\mathcal{H}^*$**

In this section we provide a characterization of those relational graph models that are (inequationally) fully abstract for $\mathcal{H}^*$. At this purpose, we introduce the notion of *hyperimmune* relational graph model (Definition 7.10), which is in some sense dual to the notion of $\lambda$-König. We prove that a relational graph model $\mathcal{D}$ is extensional and hyperimmune exactly when the induced inequational theory is the preorder $\subseteq_\mathcal{H}^*$ (Theorem 7.15).

The technique in this section is Böhm-like tree oriented, therefore it is convenient to fix some notations concerning Böhm-like trees and their interpretation.

**Notation 7.1.** We simply denote by $\mathcal{J}^*_T$ the tree $BT(\mathcal{J}^T_x)$, where $x$ is a fresh variable. Given a Böhm-like tree $V$, we write $V^*$ for the set $\{t \in NF_{\beta_\perp} \mid t \leq_\perp V\}$ of its finite approximants and we set $[V]^\mathcal{D} = \bigcup_{t \in V^*} [t]^\mathcal{D}$.

7.1. **Decomposing Infinite $\eta$-Expansions.** When considering Böhm trees of $\lambda$-terms, the infinite $\eta$-expansion $\leq_\eta^\infty$ can be decomposed into the finitary one $\leq_\eta^\infty$ followed by a more restricted infinite $\eta$-expansion $\leq_\eta^\infty$ that only allows to $\eta$-expand variables (Lemma 7.6).

Remember that the difference between $\leq_\eta^\infty$ and $\leq_\eta^\infty$ lies in the fact that the former allows countably many possibly infinite $\eta$-expansions, whereas the latter only countably many finite ones. As first noticed by Severi and de Vries in their recent work on the infinitary $\lambda$-calculus [84], in a way this difference only concerns $\eta$-expansions of variables. Consider for instance $yy \leq_\eta^\infty \lambda x.yJ^yJ^x$ and $yy \leq_\eta^\infty \lambda x.yJ^yJ^x$. The tree $\lambda x.yJ^yJ^x$ is an infinite $\eta$-expansion of $yy$, which is not a variable. Nevertheless, one can narrow down to infinite $\eta$-expansions of the variables $x$ and $y$, by noticing that $yy \leq_\eta^\infty \lambda x.yy \leq_\infty^{\infty} \lambda x.yJ^yJ^x$.

**Definition 7.2.** Let $\leq_\eta^\infty$ be the greatest relation between Böhm-like trees such that $U \leq_\eta^\infty V$ entails that:

- $U = V = \perp$,
- $or U = x$ and $V = \mathcal{J}^*_T$ for $T \in T^{\text{rec}}$,
- $or U = \lambda x_1 \ldots x_n.x_iU_1 \cdots U_k$ and $V = \lambda x_1 \ldots x_n.x_iV_1 \cdots V_k$ (for some $i, k, n \in \mathbb{N}$) where $U_j \leq_\eta^\infty V_j$ for all $j \leq k$.

**Example 7.3.** We have $\lambda x.yy \leq_\eta^\infty \lambda x.yJ^yJ^x$, whereas $yy \leq_\infty^\infty \lambda x.yJ^yJ^x$.

Clearly $\leq_\eta^\infty$ is a subrelation of $\leq_\infty^\infty$, as it is the case for $\leq_\eta^\infty$. Also notice that $\leq_\eta^\infty$ and $\leq_\eta^\infty$ are completely orthogonal relations, in the sense that $U \leq_\eta^\infty V$ and $U \leq_\eta^\infty V$ imply $U = V$.

For technical reasons we also need an inductive version of the relation $\leq_\eta^\infty$, that we denote by $\eta^\infty>$. Intuitively $U \eta^\infty> V$ means that $V$ is obtained from $U$ by performing finitely many infinite $\eta$-expansions of variables. (The notation $\eta^\infty>$ is borrowed from [84], although Severi and de Vries use the symbol for a more general notion of $\eta!$-rule.)

As we will see, actually hyperimmune relational graph models cannot distinguish between the relation $U \eta^\infty> V$ and its coinductive version $U \leq_\eta^\infty V$, in the sense expressed by the equivalence (iii $\iff$ iv) in Proposition 7.12.
Definition 7.4. Let \( \eta! \leftarrow \) be the smallest relation between Böhm-like trees closed under the following rules:

- \( U \eta! \leftarrow U \) for \( U \in \text{BT} \),
- \( x \eta! \leftarrow J_T^x \) for \( T \in \text{T}_\text{rec}^\infty \),
- \( \lambda x_1 \ldots x_n.x_1 U \cdots U_k \eta! \leftarrow \lambda x_1 \ldots x_n.x_1 V_1 \cdots V_k \) (for some \( i, k \in \mathbb{N} \)) and \( U_j \eta! \leftarrow V_j \) for all \( j \leq k \).

Notice that this can be seen as the inductive version of the coinductive Definition 7.2. Alternatively, one can define \( \Rightarrow_\eta \) as the transitive-reflexive and contextual closure of

\[
(\eta! \upharpoonright J_T^x \Rightarrow_\eta x \text{ for all } T \in \text{T}_\text{rec}^\infty).
\]

Example 7.5. Let \( U = \text{BT}(\lambda x.y.(\lambda u.x(yu))) \) and \( V = \text{BT}(\lambda x.y.(\lambda u.x(J y u))) \). These two trees are depicted in Figure 5. We have that \( U \leq_\eta V \) while \( U \eta! \not\leftarrow V \), because \( V \) is obtained from \( U \) by performing an infinite amount of \( \eta! \)-expansions of variables.

Lemma 7.6. (Decomposition of \( \leq_\eta^0 \)) Let \( M, N \in \Lambda \). We have \( \text{BT}(M) \leq_\eta^0 \text{BT}(N) \) if and only if there exists a Böhm-like tree \( W \) such that \( \text{BT}(M) \leq_\eta W \leq_\eta^0 \text{BT}(N) \).

Proof. (\( \Rightarrow \)) By transitivity of \( \leq_\text{rec}^\infty \), using the fact that both \( \leq_\eta \) and \( \leq_1^\eta \) are contained in \( \leq_\text{rec}^\infty \).

(\( \Rightarrow \)) We construct \( W \) coinductively.

In case \( M = \lambda x_1 \ldots x_n.x_1 M_1 \cdots M_k \) and \( N = \lambda x_1 \ldots x_n.x_1 N_1 \cdots N_k P_1 \cdots P_n \) where \( \text{BT}(M_j) \leq_\text{rec}^\infty \text{BT}(N_j) \) for all \( j \leq k \) and \( z_\ell \leq_\text{rec}^\infty \text{BT}(P_\ell) \) for all \( \ell \leq m \). By the coinductive hypothesis, for all \( j \) there exists \( W_j \) such that \( \text{BT}(M_j) \leq_\eta W_j \leq_\eta^0 \text{BT}(N_j) \). We then set \( W = \lambda x_{z_1} \ldots z_m.x_1 W_1 \cdots W_n z_1 \cdots z_m \). Clearly \( \text{BT}(M) \leq_\eta W \). In order to show that \( W \leq_\eta^0 \text{BT}(N) \) holds we have to prove, for all \( \ell \leq m \), that \( \text{BT}(P_\ell) = J_{T_\ell}^x \) for some \( T_\ell \in \text{T}_\text{rec}^\infty \).

Since \( z_\ell \leq_\text{rec}^\infty \text{BT}(P_\ell) \), we conclude by Proposition 2.9.

As shown in [84], the decomposition of \( \leq_\text{rec}^\infty \) could be extended to all Böhm-like trees using possibly non-recursive infinite \( \eta \)-expansions of \( x \) in the definition of \( \leq_\eta^0 \). Since here we use \( \leq_1^\eta \) in connection with hyperimmune relational graph models (Proposition 7.12), a semantic notion only concerning recursive trees, it is crucial to use our restricted version.

Lemma 7.7. Let \( U, V \) be two Böhm-like trees such that \( U \leq_\eta V \) and \( t \in U^* \). Then there exists a Böhm-like tree \( W \) such that \( U \leq_\eta^0 W \eta! \leftarrow V \) and \( t \in W^* \).

Proof. We proceed by induction on \( t \).

- If \( t = \perp \) it suffices to take \( W = V \).
- If \( t = U = x \) and \( V = J_T^x \) we get the thesis by taking \( W = U \).
• If \( t = \lambda \bar{x}.x_1t_1 \cdots t_k \), then \( U = \lambda \bar{x}.x_1U_1 \cdots U_k \) and \( V = \lambda \bar{x}.x_1V_1 \cdots V_k \) where \( t_j \in U_j^* \) and \( U_j \leq J \) \( V_j \) for all \( j \leq k \). By induction hypothesis for each \( j \) we get some \( W_j \) such that \( U_j \leq J \) \( W_j \) and \( t_j \leq W_j \). We conclude by setting \( W = \lambda \bar{x}.x_1W_1 \cdots W_k \).

**Example 7.8.** Let \( U, V \) be the trees from Example 7.5 (and Figure 5) and let \( t = \lambda xy.xy \perp \in U^* \). A possible Böhm-like tree \( W \) given by Lemma 7.7 is the following:

\[
\begin{array}{c}
\begin{array}{c}
\lambda xy.x \\
\downarrow \\
y \\
\downarrow \\
\lambda z_1.y \\
\downarrow \\
\lambda z_2.z_1 \\
\vdots \\
\vdots
\end{array}
\end{array}
\]

**Lemma 7.9.** Let \( U, V \) be two Böhm-like trees such that \( U \leq J \) \( V \) and let \( t \in V^* \). Then there exists a Böhm-like tree \( W \) such that \( U \leq J \) \( W \leq J \) \( V \) and \( t \in W^* \).

**Proof.** We proceed by induction on \( t \).

If \( t = \perp \) we take \( W = U \).

Let \( t = \lambda \bar{x}_1z_1 \cdots z_m.x_1t_1 \cdots t_k t'_1 \cdots t'_m \leq \perp V = \lambda \bar{x}_1z_1 \cdots z_m.x_1V_1 \cdots V_k V'_1 \cdots V'_m \) and let \( U = \lambda \bar{x}_1z_1 \cdots z_m.x_1U_1 \cdots U_k \) be such that \( U_j \leq J \) \( V_j \) for all \( j \leq k \) and \( z_i \leq J \) \( V'_i \) for all \( t \leq m \). For each \( j \leq k \), since \( t_j \in V_j^* \), the induction hypothesis gives some \( W_j \) satisfying \( U_j \leq J \) \( W_j \leq J \) \( V_j \) and \( t_j \in W_j^* \). We conclude by setting \( W = \lambda \bar{x}_1z_1 \cdots z_m.x_1W_1 \cdots W_k W_1 \cdots W_m \).

### 7.2. Hyperimmune Relational Graph Models

In Section 6 we exploited the Morris Separation (Theorem 2.14) to reduce the problem of being fully abstract for \( \mathcal{H}^+ \) to the property \( [x] \neq [J_T x] \), namely \( W_D(T) = [x] - [J_T x] \neq \emptyset \), for every tree \( T \in T_{\text{rec}}^\infty \). The notion of \( \lambda \)-König relational graph model provided that. Here there is a similar phenomenon: we exploit the decomposition seen above (Lemma 7.6) to reduce the full abstraction for \( \mathcal{H}^* \) to the property \( [x] = [J_T x] \), namely \( W_D(T) = [x] - [J_T x] = \emptyset \), for every \( T \in T_{\text{rec}}^\infty \). This is the intuition behind the following definition, which is some kind of dual of \( \lambda \)-König.

**Definition 7.10 (Hyperimmune models).** An rgm \( D \) is hyperimmune if for every \( T \in T_{\text{rec}}^\infty \) \( W_D(T) = \emptyset \).

The name refers to a standard concept in computability theory: a function \( f : \mathbb{N} \to \mathbb{N} \) is called hyperimmune if it is not bounded (upwardly) by any recursive function. One can prove that a relational graph model \( D \) is hyperimmune exactly when it only admits witnesses that follow hyperimmune functions. This observation justifies the choice of the terminology. The notion of hyperimmunity first appeared in these terms in [16] for Krivine’s models.

**Example 7.11.** The model \( D_\omega \) of Example 3.10 is hyperimmune. As a matter of fact, since the model is freely generated by the equation \( \ast = \omega \to \ast \), it is easy to verify that no element of \( D_\omega \) can be a witness for any \( T \in T_{\text{rec}}^\infty \) following any infinite path \( f \).

In the hypothesis of extensionality, this notion admits some additional characterizations.

**Proposition 7.12.** Let \( D \) be an extensional rgm. The following statements are equivalent:

(i) \( D \) is hyperimmune,
Then we have for some Bohm-like trees $U, V$, 

$$\left[ x \right] \subseteq [\mathbf{J}_T x] \text{ for all } T \in T^\infty_{\text{rec}},$$

$$\left[ U \right] \subseteq [V] \text{ for all Bohm-like trees } U, V,$$

$$U \leq^\eta V \text{ implies } \left[ U \right] \subseteq [V] \text{ for all Bohm-like trees } U, V.$$

**Proof.** (i $\iff$ ii) By Proposition 6.4 and Corollary 4.9 an extensional rgm $D$ is hyperimmune if and only if, for all $T \in T^\infty_{\text{rec}}$, we have that $\left[ x \right] - [\mathbf{J}_T x] = \left\{ \alpha \in D \mid x : [\alpha] \not\in [\mathbf{J}_T x] : [\alpha] \right\} = \mathcal{W}_D(T) = \emptyset$. This is equivalent to requiring that $\left[ x \right] \subseteq [\mathbf{J}_T x]$ for all $T \in T^\infty_{\text{rec}}$.

(ii $\Rightarrow$ iii) By a straightforward induction on the derivation of $\left[ U \right]$.

(iii $\Rightarrow$ iv) Suppose that there exist two Bohm-like trees $U, V$ such that $U \leq^\eta V$ and $[U] \not\subseteq [V]$. Since $[U] = \bigcup_{t \in U\ast} [t]$, there is a $t \in U\ast$ such that $[t] \not\subseteq [V]$. By Lemma 7.7 there exists $W \ni^\eta V$ such that $t \in W\ast$. Since $[W] = \bigcup_{t \in W\ast} [t]$, we get $[W] \not\subseteq [V]$, whereas $[W] \subseteq [V]$ by (iii).

(iv $\Rightarrow$ iii) Trivial, since the relation $\ni^\eta$ is included in $\leq^\eta$.

**Lemma 7.13.** Let $D$ be an extensional rgm and let $U, V$ be two Bohm-like trees. We have that $U \leq^\infty V$ implies $[V] \subseteq [U]$.

**Proof.** By Lemma 7.9, if $t \in V\ast$ then $t \in W\ast$ for some $U \leq^\eta W$. So $[t] \subseteq [W] = [U]$, where the equality holds by extensionality. Since $[V] = \bigcup_{t \in V\ast} [t]$, we get $[V] \subseteq [U]$.

In general, the hypothesis $U \leq^\infty V$ does not imply $[U] \subseteq [V]$, even in presence of extensionality. This implication only holds when the model is in addition hyperimmune.

**Lemma 7.14.** Let $D$ be an extensional and hyperimmune rgm and let $M, N \in \Lambda$. Then $\mathcal{B}T(M) \leq^\infty \mathcal{B}T(N)$ implies $[M] \subseteq [N]$.

**Proof.** By Lemma 7.6 there exists a Bohm-like tree $W$ such that $\mathcal{B}T(M) \leq^\eta W \leq^\eta \mathcal{B}T(N)$. Then we have $[\mathcal{B}T(M)] \subseteq [W]$ by extensionality and $[W] \subseteq [\mathcal{B}T(N)]$ by the characterization (iv) of hyperimmunity provided by Proposition 7.12. By transitivity we obtain $[\mathcal{B}T(M)] \subseteq [\mathcal{B}T(N)]$, so we conclude $[M] \subseteq [N]$ by Theorem 4.16.

The following theorem constitutes the main result of the section. It is actually an adaptation to relational graph models of the characterization of fully abstract Krivine’s models provided in [16, 17].

**Theorem 7.15.** Let $D$ be an rgm. The following statements are equivalent:

(i) $D$ is extensional and hyperimmune,

(ii) $D$ is inequationally fully abstract for $\subseteq_{H\ast}$,

(iii) $D$ is fully abstract for $H^\ast$.

**Proof.** (i $\Rightarrow$ ii) We must prove that $M \subseteq_{H\ast} N$ if and only if $[M] \subseteq [N]$. The right-to-left implication is true for all rgm’s, since they are sensible (Corollary 4.17) and $\subseteq_{H\ast}$ is the maximal sensible inequational theory. Let us prove the left-to-right implication.

By Theorem 2.5 the hypothesis $M \subseteq_{H\ast} N$ means that $\mathcal{B}T(M) \leq^\infty U \leq^\infty V \geq^\infty N \mathcal{B}T(N)$ for some Bohm-like trees $U$ and $V$. In particular $U$ can be taken of the form $U = \mathcal{B}T(P)$ for some $P \in \Lambda$ (see [7, Ex. 10.6.7]). Then we have

$$[M] \subseteq [P] \text{ by Lemma 7.14}$$

$$= [U] \text{ by Theorem 4.16}$$

$$\subseteq [V] \text{ by def. of } [-] \text{ for Bohm-like trees}$$

$$\subseteq [\mathcal{B}T(N)] \text{ by Lemma 7.13}$$

$$= [N] \text{ by Theorem 4.16.}$$
(ii ⇒ iii) Trivial.

(iii ⇒ i) The theory $H^*$ is extensional, so that is the case for any fully abstract rgm. Moreover, the theory $H^*$ satisfies $x \sqsubseteq_{H^*} J_T x$ for all $T \in T^\infty_{rec}$. So the model is hyperimmune by the characterization (ii) of hyperimmunity provided by Proposition 7.12.

As a consequence, we get that the model $D_\omega$ has the same inequational and $\lambda$-theories as Scott’s $D_\infty$ [81], namely it is fully abstract for $H^*$. Such a result first appeared in [65].

**Corollary 7.16.** The model $D_\omega$ of Example 3.10 is inequationally fully abstract for $\sqsubseteq_{H^*}$. In particular $\text{Th}(D_\omega) = H^*$.

8. Conclusions

We have studied the class of the relational graph models living inside the relational semantics of $\lambda$-calculus, and proved that they all enjoy the Approximation Theorem. We exhibited a model inducing the minimum relational (in)equational graph theory, and provided sufficient and necessary conditions for a relational graph model to be fully abstract for $H^+$ (resp. $H^*$). Actually such characterizations of full abstraction hold more generally for all relational models, since these theories are extensional and the class of extensional relational graph models coincide with the class of extensional reflexive objects in $\text{MRel}$.

We conclude presenting some open problems that we consider interesting.

**Problem 1.** It is well known that the $\lambda$-theory $H^*$ satisfies the $\omega$-rule [7, Def. 4.1.10], and the analogous result was recently proved for $H^+$ in [18]. Does every extensional graph model satisfy the $\omega$-rule?

**Problem 2.** Are all $\lambda$-theories in the interval $[H^+, H^*]$ relational graph theories? If it is not the case, is it possible to provide a characterization of the representable ones?

**Acknowledgements.** We would like to thank Henk Barendregt, Mariangiola Dezani, Thomas Ehrhard, Jean-Jacques Lévy, Michele Pagani, Andrew Polonsky and Simona Ronchi Della Rocca for many interesting discussions on relational models and the $\lambda$-theory $H^+$. We also wish to thank the anonymous reviewers for their valuable comments and suggestions to improve the quality of the paper.
