\textbf{Abstract.} For many a natural deduction style logic there is a Hilbert-style logic that is equivalent to it in that it has the same theorems (i.e. valid judgements $\Gamma \vdash P$ where $\Gamma = \emptyset$). For intuitionistic implicational logic, the axioms of the equivalent Hilbert-style logic can be propositions which are also known as the types of the combinators $\mathbf{I}$, $\mathbf{K}$ and $\mathbf{S}$.

Natural deduction versions of illative combinatory logics have formulations with axioms that are actual type statements for $\mathbf{I}$, $\mathbf{K}$ and $\mathbf{S}$. As pure type systems (PTSs) are, in a sense, equivalent to systems of illative combinatory logic, it might be thought that Hilbert style PTSs (HPTSs) could be based in a similar way.

This paper shows that some PTSs have very trivial equivalent HPTSs, with only the axioms as theorems and that for many PTSs no equivalent HPTSs can exist. Most commonly used PTSs belong to these two classes.

For some PTSs however, including $\lambda^*$ and the PTS at the basis of the proof assistant Coq, there is a nontrivial equivalent HPTS, with axioms that are type statements for $\mathbf{I}$, $\mathbf{K}$ and $\mathbf{S}$.

\section*{Introduction}

Most early logical systems (for propositional and predicate logic) allowed no hypotheses and so had no rules for introducing or cancelling them. These could be represented by a finite set of axiom schemes and rules of inference such as modus ponens and generalisation.

Later natural deduction systems which did allow hypotheses had fewer axiom schemes but required introduction and elimination rules for hypotheses. Herbrand showed that classical Hilbert style and natural deduction style propositional and predicate logics had the same theorems (i.e. judgements with empty contexts).

\textit{2000 Mathematics Subject Classification:} 03B40, 03B70, 68N18.

\textit{Key words and phrases:} Hilbert-style logics, pure type systems, type theory, lambda calculus, illative combinatory logic.

\textsuperscript{a,b} The authors would like to thank the anonymous referees for their useful comments.
Pure type systems (PTSs), defined below, have two rules that introduce hypotheses and two that cancel them. In this paper we answer a question of Fairouz Kamareddine “Are there Hilbert style PTSs?”. When we define Hilbert style PTSs (HPTSs) as PTSs with empty contexts, with a finite set of extra axiom schemes, with $s_1, s_2, s_3, \ldots$ representing arbitrary sorts, and some extra rules, it is obvious that there are HPTSs. We will be interested in whether, for PTSs, there are theorem equivalent HPTSs. We will answer this question for a number of classes of PTSs which include all the PTSs, from the standard literature, that we have examined. The methods we use, for proving that a HPTS is equivalent to a PTS, are along the lines of those of Herbrand, but rather more complex.

Just as combinator based programming languages, requiring no free, or in fact, no variables, have proved useful in practice, perhaps an HPTS, which also requires no (free) variables, that is theorem equivalent to a PTS may be useful. Also, perhaps some metatheoretical results may be proved more easily for an HPTS than for the equivalent PTS.

1. Pure Type Systems

Each Pure Type System (PTS) $\lambda X$ has a set of variables $V$, a set of constants $C$, a set of “sorts” $S \subseteq C$. It has a class of pseudoterms given by $T = V \cup C \cup (\Pi X : T \cdot T) \cup (\lambda X : T \cdot T) \cup TT$. If $M$ and $N$ are pseudoterms, $M : A$ is a statement, $\Gamma$ is a context if it is a sequence of statements; $\Gamma \vdash M : A$ is then called a judgement. A PTS has a set of axioms $A$ each of the form $c : s$ where $c \in C$ and $s \in S$. Then it has a set $R$ of triples $\langle s_1, s_2, s_3 \rangle \in S^3$, which determine under what conditions a term $\Pi x : A. B$ is in a sort. Most PTSs are known by a “specification” $\langle S, A, R \rangle$ (as usually $C = S$).

The PTS postulates are as follows:

(axiom) \[ \frac{c : s \in A}{\vdash c : s} \]

(start) \[ \frac{\Gamma \vdash A : s}{\Gamma, x : A \vdash x : A} \]

(weakening) \[ \frac{\Gamma \vdash M : B \quad \Gamma \vdash A : s \quad x \notin FV(\Gamma)}{\Gamma, x : A \vdash M : B} \]

(application) \[ \frac{\Gamma \vdash M : (\Pi X : A. B) \quad \Gamma \vdash N : A}{\Gamma \vdash MN : B[x := N]} \]

(abstraction) \[ \frac{\Gamma, x : A \vdash M : B \quad \Gamma \vdash (\Pi X : A. B) : s}{\Gamma \vdash (\lambda X : A. M) : (\Pi X : A. B)} \]

(product) \[ \frac{\Gamma, x : A \vdash B : s_2 \quad \Gamma \vdash A : s_1 \quad (s_1, s_2, s_3) \in R}{\Gamma \vdash (\Pi X : A. B) : s_3} \]

(conversion) \[ \frac{\Gamma \vdash M : A \quad \Gamma \vdash B : s \quad A = \beta B}{\Gamma \vdash M : B} \]

When there are two judgements as premises in a rule, we call the left one the major premise and the right one the minor premise.

Later we will need the following definition:
Definition 1.1 (Inhabited and Normal Form Inhabited Sorts).

s is an inhabited sort (s ∈ I) if ⊢ A : s for some A.
s is a normal form inhabited sort (s ∈ N) if for some term A in normal form, ⊢ A : s.

The translation [ ] of Bunder and Dekkers [3] translates the pseudoterms and statements of PTSs into terms of illative combinatory logic (ICL) as follows:

\[ [x] = x, \quad [c] = c, \quad [XY] = [X][Y] \]

\[ [X : A] = [A][X], \quad [\Pi x : X. \ y] = G[X][y] \quad (x \notin \text{FV}(XY)) \]

where \( G = \lambda xyz. \Xi x(Syz) \) (S is the combinator equivalent to \( \lambda xyz. xz(yz) \)). Terms in ICL can be represented without any free variables at all using the combinators S and K (equivalent to \( \lambda x. yx \)). \( \Xi xy \) represents roughly \( (\forall u \in x)y(u) \) or \( x \subseteq y \).

ICL, designed as a foundation for logic and mathematics, has a rule like (abstraction) which was derived in Bunder [2] from a set of axioms. In Section 6 we will see how the methods developed there lead to the ones used here. The main difference between PTSs and standard ICLs, other than the lack of distinction between terms and types, lies in the (abstraction) rule. The direct counterpart to the ICL rule would have \( \Gamma \vdash A : s \), for \( \Gamma \vdash (\Pi x : A.B) : s \). This is the most important factor in making it difficult to have equivalent Hilbert-style PTSs.

2. Hilbert-style PTSs

We define Hilbert-style PTSs as follows:

Definition 2.1 (HPTS). Each Hilbert style Pure Type System (HPTS) has \( V, C, S, T \), statements, contexts and judgements as for PTSs, except that the contexts are always empty. A HPTS has a set of sorts \( S \) and a set of axioms \( A \), as for PTSs, and an additional finite set \( B \) of axiom schemes in which “sort variables” can be replaced by sorts. Most HPTSs are known by a “specification” \( (S, A, R) \) (as usually \( C = S \)). A HPTS has the PTS (application) and (conversion) rules (with empty contexts) as well as:

\[
\text{(type reduction)} \quad \vdash M : A \quad A \to B \quad \vdash M : B.
\]

\[
\text{(subject reduction)} \quad \vdash M : A \quad M \to N \quad \vdash N : A.
\]

Note the latter rules are derivable for all PTSs, for HPTSs neither is, even using (conversion).

Definition 2.2 (Equivalent HPTS). If \( \lambda X \) is a PTS with specification \( (\mathcal{S}, A, \mathcal{R}) \), a HPTS \( \lambda X^h \), with specification \( (\mathcal{S}, A, B) \) will be equivalent if

\[
(\forall M, A)(\vdash^X M : A \iff \vdash^{X^h} M : A).
\]

Here \( \vdash^X \) stands for provability in \( \lambda X \) and \( \vdash^{X^h} \) in \( \lambda X^h \). If the PTS is arbitrary or obvious from the context we use \( \vdash \) and \( \vdash^h \). \( B \) will be a function of \( \mathcal{R} \), i.e. it will include axioms such as \( \vdash^h [\lambda u : s_1. \lambda v : (\Pi x : u.s_2). \Pi x : u.vx] \) : \( [\Pi u : s_1. \Pi v : (\Pi x : u.s_2). s_3] \) if \( (s_1, s_2, s_3) \in \mathcal{R} \).
Below are some PTSs that have been studied in the literature (particularly Barendregt [1] and Geuvers [4]).

In $\lambda^\nu, S = \{\ast\}, C = \{\ast, 0\}$, in all other cases $C = S$ consists of all the constants visible in $A$ and $R$. $(s_1, s_2)$ is used as an abbreviation for $(s_1, s_2, s_2)$.

\[
\begin{align*}
\lambda^\nu & \quad A = \{\ast : \boxdot\} \quad R = \{\{\ast, \ast\}\} \\
\lambda^\gamma & \quad A = \{0 : \ast\} \quad R = \{\{\ast, \ast\}\} \\
\lambda^\lambda & \quad A = \{\ast : \ast\} \quad R = \{\{\ast, \ast\}\} \\
\lambda^2 & \quad A = \{\ast : \boxdot\} \quad R = \{\{\ast, \ast\} \ast \boxdot, (\boxdot, \ast)\} \\
\lambda^P & \quad A = \{\ast : \boxdot\} \quad R = \{\{\ast, \ast\} \ast \boxdot, (\ast \ast \boxdot)\} \\
\lambda^\omega & \quad A = \{\ast : \ast\} \quad R = \{\{\ast, \ast\} \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast \ast
\end{align*}
\]

The PTS used in the proof assistant Coq we will call $\lambda$Coq. It has as axioms:

\[ \vdash \ast : \boxdot_1 \quad \vdash \ast s : \boxdot_1 \quad \forall i \in \mathbb{N} : \vdash \boxdot_i : \boxdot_{i+1}. \]

More axioms are generated by

\[ A : B, B : C \in A \quad \Rightarrow \quad A : C \in A. \]

In early versions $R$ is given by

\[ (\ast s, \ast s), (\ast p, \ast p), (\ast s, \ast p), (\ast p, \ast s), (\ast p, \boxdot_1), (\ast s, \boxdot_1), (\boxdot_i, \ast p), (\boxdot_i, \ast s), (\boxdot_i, \boxdot_j, \square_{\max(i,j)}) \in R. \]

for all $i, j \in \mathbb{N}$. Coq 8.0 replaces $(\boxdot_i, \ast s) \in R$ by $(\boxdot_i, \ast s, \boxdot_i) \in R$.

We will be able to determine whether or not there are equivalent HPTSs for all of the above.
3. SOME PTS LEMMAS AND DEFINITIONS

We now state a number of standard lemmas for PTSs. Most proofs can be found in Barendregt [1] or Bunder and Dekkers [3].

**Lemma 3.1** (Free Variable Lemma). If \( x_1 : A_1, \ldots, x_n : A_n \vdash M : B \), then

(i) \( x_1, \ldots, x_n \) are distinct;
(ii) \( FV(M, B) \subseteq \{x_1, \ldots, x_n\} \);
(iii) \( FV(A_i) \subseteq \{x_1, \ldots, x_{i-1}\} \) for \( 1 \leq i \leq n \).

**Lemma 3.2** (Substitution Lemma). If \( \Gamma_1, x : A, \Gamma_2 \vdash M : B \) and \( \Gamma_1 \vdash N : A \) then \( \Gamma_1, \Gamma_2[x := N] \vdash M[x := N] : B[x := N] \).

**Lemma 3.3** (Condensing Lemma). If \( \Gamma_1, x : A, \Gamma_2 \vdash M : B \), where \( x \notin FV(\Gamma_2, M, B) \), then \( \Gamma_1, \Gamma_2 \vdash M : B \).

**Lemma 3.4** (Generation Lemma). Let \( \Gamma \vdash M : B \). Then

(i) \( M \equiv c \in C \Rightarrow (\exists s \in S) B =_{\beta} s & \ c : s \in A \);
(ii) \( M \equiv x \Rightarrow (\exists C) B =_{\beta} C & \ x : C \in \Gamma \);
(iii) \( M \equiv \Pi x : C.D \Rightarrow (\exists s_1, s_2, s_3) (s_1, s_2, s_3) \in R & \ \Gamma \vdash C : s_1 \& \ \Gamma, x : C \vdash D : s_2 & \ B =_{\beta} s_3 \);
(iv) \( M \equiv \lambda x : C.N \Rightarrow (\exists s \in S) (\exists D) \Gamma, x : C \vdash N : D \ & \ B =_{\beta} \Pi x : C.D \ & \ \Gamma \vdash (\exists s \in S) (\exists D) \Gamma, x : C \vdash N : D \ & \ B =_{\beta} \Pi x : C.D \ & \ \Gamma \vdash D[x := Q] \).

In each case the derivations, of the judgements of the form \( \Gamma \vdash R : E \) in (iii) to (v), are shorter than that of \( \Gamma \vdash M : B \).

**Lemma 3.5** (Correctness of Types Lemma). If \( \Gamma \vdash M : B \) then \( (\exists s \in S) [B \equiv s \ or \ \Gamma \vdash B : s] \).

**Lemma 3.6** (Subject and Type Reduction Lemma). If \( \Gamma \vdash M : B \), then

(i) \( M \rightarrow_{\beta} N \ implies \ \Gamma \vdash N : B \),
(ii) and \( B \rightarrow_{\beta} A \ implies \ \Gamma \vdash M : A \).

**Lemma 3.7** (Start Lemma). If \( \Gamma \vdash M : B \), then

(i) \( (c : s) \in A \ implies \ \Gamma \vdash c : s \),
(ii) \( \Gamma \equiv x_1 : A_1, \ldots, x_n : A_n implies that for \( 0 \leq i < n \) there is an \( s \in S \) such that \( x_1 : A_1, \ldots, x_i : A_i \vdash A_{i+1} : s \).

4. PTSs where A IS THE SET OF THEOREMS

The following lemma specifies a set of PTSs whose axioms are its only theorems. The equivalent HPTS is then trivially one with no extra axioms, i.e. with \( B = \emptyset \).

**Lemma 4.1.** In a PTS satisfying

\[(\forall c, s_1)(c : s_1) \in A \Rightarrow (\exists s_2, s_3)((s_1, s_2, s_3) \in R))\]  

we have \( \vdash M : A \Leftrightarrow M : A \in A \).
Proof. We show $M : A \in A$ by induction on the derivation of

\[
\vdash M : A. \tag{4.1}
\]

(4.1) clearly does not come by (start) or (weakening).

If (4.1) comes by (application) from

\[
\vdash P : (\Pi x : C.D) \quad \text{and} \quad \vdash Q : C
\]

where $M \equiv PQ$ and $A \equiv D[x := Q]$, we have by the induction hypothesis $P : (\Pi x : C.D) \in A$, which is impossible.

If (4.1) comes by (abstraction) from

\[
x : B \vdash N : C \quad \text{and} \quad \vdash (\Pi x : B.C) : s
\]

where $M \equiv \lambda x : B.N$ and $A \equiv \Pi x : B.C$, then by the induction hypothesis $(\Pi x : B.C) : s \in A$, which is impossible.

If (4.1) comes by (product) from

\[
x : B \vdash C : s_2 \quad \vdash B : s_1 \quad \text{and} \quad (s_1, s_2, s_3) \in R
\]

where $M \equiv \Pi x : B.C$ and $A \equiv s_3$, then, by the induction hypothesis, $(B : s_1) \in A$, which is impossible by ($\$\$).

If (4.1) comes by (conversion) from

\[
\vdash M : B \quad \vdash A : s \quad \text{and} \quad A =_\beta B
\]

then by the induction hypothesis $(M : B), (A : s) \in A$. However then $A$ and $B$ must be in normal form and so $A \equiv B$ and $(M : A) \in A$.

If (4.1) is an axiom, the result holds trivially.

This implies the following theorem and corollary.

**Theorem 4.2.** A PTS satisfying ($\$\$) has an equivalent HPTS, with $B = \emptyset$, but this is trivial in that it has only its axioms as theorems.

**Corollary 4.3.** $\lambda \rightarrow$ and $\lambda P$ each have an equivalent HPTS, but $\vdash * : \Box$ is the only theorem of both systems.

5. PTSs with no Equivalent HPTS

In $\lambda \rightarrow$ and $\lambda P$ there is no term $A$ such that $\vdash A : *$ and the only theorem is $\vdash * : \Box$.

We can show, by a single (product) rule preceded by two uses of an axiom and a (start) or (weakening) rule, that in the other PTSs, given in Section 2, there are theorems that are not axioms. Most of these are given below.

**Lemma 5.1.**

(i) In $\lambda \tilde{x}$ we have $\vdash (\Pi x : 0.0) : *$.

(ii) In $\lambda^*$, $\lambda \rightarrow$, $\lambda \Pi 2$, $\lambda \omega$, $\lambda C$, $\lambda U$ and $\lambda HOL$, we have $\vdash (\Pi x : * .x) : *$.

(iii) In $\lambda \tilde{\omega}$ and $\lambda \Pi \tilde{\omega}$, we have $\vdash (\Pi x : * .*) : \Box$.

(iv) In $\lambda AUT-68$, $\lambda AUT-QE$ and $\lambda PAL$, we have $\vdash (\Pi x : * .*) : \triangle$. 

□
We now give a condition under which, in a PTS, certain sorts have an infinite number of inhabitants of the form \( \Pi x: A . B \) that are not substitution instances of each other. We show later that many PTSs with this property cannot be equivalent to HPTSs.

**Lemma 5.2.** Assume that in a PTS there is a finite sequence \( s_1, s_2, \ldots, s_n \in \mathcal{S} \) such that:

\[
(\exists n \in \mathbb{N}) \ n > 1 \ \& \ s_1 = s_n \in \mathcal{N} \ \& \ (\forall i)(1 \leq i < n \Rightarrow (\exists s' \in \mathcal{I} \ & (s', s_i, s_{i+1}) \in \mathcal{R}))
\]

then

\[
\vdash (\Pi x: A . B) : s_1
\]

for an infinite number of \( \beta \)-distinct terms \( \Pi x: A . B \) which are not \( s_i \) for \( s_j \) substitution instances of each other.

**Proof.** Assume that we have \((s_1, \ldots, s_n)\) for \( s_1, s_2, \ldots \in \mathcal{S}\).

As \( s_1 \in \mathcal{N} \) we have, for some \( A_1 \), in normal form

\[
\vdash A_1 : s_1.
\]

Now we show, by induction on \( i \) that, for \( 1 < i \leq n \), there is a \( B_{i-1} \) and an \( A_i = \Pi x_{i-1} : B_{i-1} . A_{i-1} \) such that

\[
\vdash A_i : s_i. \tag{5.1}
\]

For each \( i \) we have, by \((s_1, \ldots, s_n)\), an \( s' \) such that \((s', s_{i-1}, s_i) \in \mathcal{R} \) and a \( B_{i-1} \) such that

\[
\vdash B_{i-1} : s'.
\]

When \( i = 2 \) we have \( \vdash A_1 : s_1 \) above, otherwise we have \( \vdash A_{i-1} : s_{i-1} \) by the induction hypothesis. By (weakening) we have

\[
x_{i-1} : B_{i-1} \vdash A_{i-1} : s_{i-1}
\]

and by (product) we have \((5.1)\). So \((5.1)\) holds for \( 1 \leq i \leq n \) and, as we have \( s_1 = s_n \),

\[
\vdash A_n : s_1.
\]

Repeating the above, with \( A_n \) for \( A_1 \), we get \( \vdash A_{2n-1} : s_1 \) and similarly \( \vdash A_{3n-2} : s_1, \ldots \)

If \( A_{in-i+1} = B_j \ A_{jn-j+1} \) for \( i < j \), then

\[
\Pi x_{i-n} : B_{in-i} . A_{in-i} = B_j \ A_{jn-j} : B_{jn-j} . A_{jn-j}
\]

and so \( A_{in-i} = B_j \ A_{jn-j} \) and eventually

\[
A_1 = B_{(j-i)(n-1)+1}.
\]

But \( A_1 \) is a proper part of \( A_{(j-i)(n-1)+1} \) and is in normal form, which is impossible. Hence \( A_n, A_{2n-1}, A_{3n-2}, \ldots \) are \( \beta \)-distinct inhabitants of \( s \) all of the form \( \Pi x: A . B \) which are not substitution instances of each other. \( \square \)

\((s_1, \ldots, s_n)\) is satisfied for many sequences \( s_1, s_2, \ldots, s_n \) and many PTSs. Here we list one such sequence and sort for most of the PTSs given in Section 2.

**Lemma 5.3.**

(i) \( \lambda^\tau, \lambda^* \) and \( \lambda^2 \) satisfy \((\ast, \ast)\).

(ii) \( \lambda_{\square}, \lambda_{\Box}, \lambda_{P2}, \lambda_{P2^c}, \lambda_{C}, \lambda_{U} \) and \( \lambda_{HOL} \) satisfy \((\Box, \Box)\).

(iii) \( \lambda_{AUT-68}, \lambda_{AUT-QE} \) and \( \lambda_{PAL} \) satisfy \((\triangle, \triangle)\).
Proof.
(i) By Lemma 5.1(i), (ii) with $s' = *$.
(ii) For $\lambda P2$, by Lemma 5.1(ii), with $s' = *$. For the others with $s' = \Box$.
(iii) By Lemma 5.1(iv) with $s' = \Box$.

Now we can prove the main result in the section.

**Theorem 5.4.** If, in a PTS $\lambda X$, ($s_1, \ldots, s_n$) holds for some $s_1, \ldots, s_n \in S$ and
\[(\forall s'_1, s'_2, s'_3)((s'_1, s'_2, s'_3) \in R \Rightarrow (s_1 : s'_2) \notin A),\]
then there is no HPTS equivalent to $\lambda X$.

Proof. By Lemma 5.2, if ($s_1, \ldots, s_n$) holds we have, for an infinite number of $\beta$-distinct terms $\Pi x : A.B$, which are not substitution instances of each other
\[\vdash (\Pi x : A.B) : s_1.\]

Suppose that there is an equivalent $\lambda X^h$.

As a HPTS has only a finite set of axioms $B$, at least some must be derived, in $\lambda X^h$, by (application) and perhaps (conversion), (type reduction) and (subject reduction) from
\[\vdash^h P : (\Pi y : D.E) \text{ and } \vdash^h Q : D\]
where $PQ \rightarrow_\beta \Pi x : A.B$ and $E[y := Q] \rightarrow_\beta s_1$. By the equivalence of $\lambda X$ and $\lambda X^h$ also:
\[\vdash P : (\Pi y : D.E) \text{ and } \vdash Q : D.\] (5.2)

So by correctness of types (Lemma 3.5), for some $s'_3 \in S$
\[\vdash (\Pi y : D.E) : s'_3\]
and by the Generation Lemma (Lemma 3.4(iii)) we have:
\[\vdash D : s'_1 \text{ and } y : D \vdash E : s'_2\]
where $(s'_1, s'_2, s'_3) \in R$.

Now by the substitution lemma (Lemma 3.2, 5.2) and, if needed, subject reduction (Lemma 3.6) $\vdash s_1 : s'_2$.

By Lemma 3.4(i) this contradicts ($$s_1$), so $\lambda X$ has no HPTS equivalent. \[\square\]

**Theorem 5.5.** $\lambda^\tau$, $\lambda 2$, $\lambda \omega$, $\lambda_\omega$, $\lambda P2$, $\lambda P\omega$, $\lambda C$, $\lambda AUT-68$, $\lambda AUT-QE$, $\lambda PAL$, $\lambda U$ and $\lambda HOL$ have no equivalent HPTSs.

Proof. By Lemma 5.3 and Theorem 5.4. \[\square\]

Note that ($$s$) is not satisfied by any sort $s$ in $\lambda^\tau$ and $\lambda Coq$. For $\lambda^- ($$s\ast$) holds but ($s\ast, s_2, \ldots, \ast$) does not for any $s_2, \ldots$ For $\lambda P ($$s\ast$) fails, ($$\Box\varnothing$) holds but ($\Box\varnothing, s_2, \ldots, \Box\varnothing$) does not for any $s_2, \ldots$.
6. How to Prove (abstraction) and (product)

In implicational logic the \( \vdash \) introduction rule is \( \Gamma, A \vdash B \Rightarrow \Gamma \vdash A \supset B \). The hypothesis \( A \) in \( \Gamma, A \vdash B \) is cancelled in \( \Gamma \vdash A \supset B \). This rule is proved in a Hilbert-style system by induction on the number of steps in a derivation that allows hypotheses. We assume that an hypothesis can be cancelled in the previous step (or steps) and use this to show it can be cancelled in the next. In intuitionistic and classical implicational logic three cases are needed and each requires the Hilbert-style system to have a particular axiom or theorem.

If the hypothesis \( p \) is itself the step in the deduction we need

\[ \vdash p \supset p. \]

If the deduction step is an axiom or another hypothesis than \( p \) we need

\[ \vdash q \supset p \supset q. \]

If the deduction step comes by modus ponens from

\[ p \vdash q \quad \text{and} \quad p \vdash q \supset r, \]

we need

\[ \vdash (p \supset q \supset r) \supset (p \supset q) \supset p \supset r. \]

Note that the three theorems we require represent the simple types of the combinators \( I, K \) and \( S \) (when \( \supset \) is replaced by \( \rightarrow \)).

In illative combinatory logic, the introduction rule for \( \Xi \) (restricted generality) is \( \Gamma, Ax \vdash Bx \Rightarrow \Gamma, L Ax \vdash \Xi AB \), where \( L \) is a constant, \( x \notin FV(\Gamma, A, B) \) and \( Ax \) is the hypothesis being cancelled. In the proof of this rule in a Hilbert-style system,(see Bunder[2]), the first two cases are similar to those for the proof of implicational introduction. The third is the case where \( \Gamma, Ax \vdash DM \) is derived from \( \Gamma, Ax \vdash \Xi CD \) and \( \Gamma, Ax \vdash CM \). Again, by induction, we assume that the \( \Xi \)-introduction step can be applied to the previous steps.

The axioms of the Hilbert-style system, when rewritten with \( U \rightarrow V \) for \( FU \equiv \lambda x.\Xi U(\lambda y.V(xy)) \) are:

\[ \vdash \ldots [(A \rightarrow A) I] \]
\[ \vdash \ldots [(A \rightarrow B \rightarrow A) K] \]
\[ \vdash \ldots [(A \rightarrow B \rightarrow C) \rightarrow (A \rightarrow B) \rightarrow A \rightarrow C) S] \]

where \( \ldots \) represent conditions involving \( L \) on \( A, B \) and \( C \).

These are type assignment statements for \( I, K \) and \( S \).

It might be thought that this same technique could be employed for PTSs, using type assignment statements for \( I, K \) and \( S \), of the form \( \vdash (\ldots I) : (\ldots A \rightarrow A) \) etc and with hypotheses of the form \( x : A \). This however may not work.

If we have a PTS with \( (c : s_1) \in A \) and can prove \( x : c \vdash B : s_2 \) and/or \( x : c \vdash M : B \), perhaps with \( M \equiv x, c \equiv B \), it may be that (product) and (abstraction) cannot be applied because \( (s_1, s_2, s_3) \notin \mathcal{R} \) for any \( s_3 \).

This does not mean that \( x : c \) can never be cancelled. We may obtain:

\[ x : c \vdash P : (\Pi y : D.E) \quad \text{and} \quad x : c \vdash Q : D \]

where \( x : c \) cannot be cancelled, as, even if we have

\[ x : c \vdash (\Pi y : D.E) : s_2 \quad \text{and} \quad x : c \vdash D : s_3, \]
and additional axioms of Axiom S1 ⊢ and by (abstraction) we have λPTSs that have equivalent HPTSs are corresponding to it.

\[ \lambda \text{PTS} \text{ and } (\Pi x.c.PQ) : s_7, \text{ we can cancel } x : c \text{ to give } \]
\[ \vdash (\lambda x.c.PQ) : (\Pi x.c.E[y := Q]). \]

This PTS therefore does have theorems not in A, but it is hard to determine the HPTS corresponding to it.

7. Supersorted PTSs

PTs that have equivalent HPTSs are λ* and λCoq (both versions), but these belong to a larger class that has the following property:

**Definition 7.1** (Supersorted). A PTS is said to be supersorted if:

\[ (\forall c \in C)(\exists s \in S) (c : s) \in A \text{ and } (\forall s_1, s_2 \in S) (\exists s_3 \in S) (s_1, s_2, s_3) \in R. \]

For supersorted PTSs (abstraction) can be simplified.

**Theorem 7.2.** In every supersorted PTS (abstraction) can be replaced by:

\[ \Gamma, x : A \vdash M : B \]
\[ \Gamma \vdash (\lambda x.A.M) : (\Pi x.A.B). \]

**Proof.** If

\[ \Gamma, x : A \vdash M : B \]
by Lemmas 8.7(ii) and 8.5 we have, for some s_1, s_2 \in S:

\[ \Gamma \vdash A : s_1 \text{ and either } \Gamma, x : A \vdash B : s_2 \text{ or } B = s \text{ for some } s \in S. \]

If the PTS is supersorted we have, for some s_2, (s : s_2) \in A in the latter (B = s) case, and so the result of the former case by Lemma 5.7(1).

Hence by (product) and supersortedness we have, for some s_3 \in S,

\[ \Gamma \vdash (\Pi x.A.B) : s_3 \]
and by (abstraction) we have

\[ \Gamma \vdash (\lambda x.A.M) : (\Pi x.A.B). \]

For a supersorted PTS λX we define a corresponding HPTS λX^h, which in Theorem 9.4 is shown to be equivalent to λX^h.

**Definition 7.3** (Corresponding HPTS). If λX is a supersorted PTS with specification (S, A, R) the corresponding HPTS λX^h has specification (S, A, B), with as members of B the following theorems of λX:

**Axiom Pi** \[ \vdash \Pi \lambda u.s_1,\lambda v.(\Pi x.u.s_2).\Pi x.v.vx \vdash \Pi u.s_1,\Pi v.(\Pi x.u.s_2).s_3 \text{ for } (s_1, s_2, s_3) \in R. \]

**Axiom I1** \[ \vdash \Pi \lambda x.s_1,\lambda y.(\Pi x.y.x).\Pi x.s_1,\Pi y.x. \]

**Axiom K1** \[ \vdash \Pi \lambda y.s_1,\lambda y.s_2,\lambda z.z.(\lambda w.y.z) \vdash \Pi x.s_1,\Pi y.s_2,\Pi x.x.\Pi u.y.x. \]

**Axiom S1** \[ \vdash \Pi \lambda v.s_1,\lambda v.(\Pi x.u.s_2).\lambda t.(\Pi x.u.(\Pi y.vx.s_3)).\lambda w.(\Pi x.u.(\Pi y vx.txy)).\lambda z.(\Pi x.u.vx)(zx) \vdash (\Pi u.s_1,\Pi u.s_2,\Pi t.(\Pi x.u.(\Pi y.vx.s_3)).\Pi w.(\Pi x.u.(\Pi y vx.txy)).\Pi z.(\Pi x.u.vx),\Pi x.u.t(xz)). \]

and additional axioms of B generated by (I) and (II):
(I) If \((M : A) \in B\), \(A \notin \mathcal{S}\) and \(A'\) is obtained from \(A\) by replacing any second occurrence of an \(s_i\) in \(A\) by any \(s_j\) not in \(A\), then if \(\vdash A' : s\) for \(s \in \mathcal{S}\), \((A' : s) \in B\). Any conditions on \((M : A) \in B\) not required in the proof of \(\vdash A' : s\) are not part of the new axiom.

(II) If \(\left(\lambda x_1 : A_1 \ldots \lambda x_{i-1} : A_{i-1} \cdot \Pi x_i : A_i, B\right) : \left[\Pi x_1 : A_1 \ldots \Pi x_{i-1} : A_{i-1} \cdot s\right] \in B\) and \(s' \in B\) satisfies \(\vdash \left(\lambda x_1 : A_1 \ldots \lambda x_i : A_i, B\right) : \left(\Pi x_1 : A_1 \ldots \Pi x_i : A_i, s'\right)\), then

\[
\left(\lambda x_1 : A_1 \ldots \lambda x_i : A_i, B\right) : \left[\Pi x_1 : A_1 \ldots \Pi x_i : A_i, s'\right] \in B.
\]

**Note.** The \(s_1, s_2, \ldots\) in Axioms I1, K1 and S1 are sort variables that can be replaced by arbitrary elements of \(\mathcal{S}\). In the axioms generated by (I) and (II) there are restrictions on the sorts that can be substituted for such variables based on the PTS provability of the judgements mentioned.

Given a PTS \(\lambda X\), we will assume below that \(\lambda X^h\) is the corresponding HPTS.

**Theorem 7.4.** If, for a supersorted PTS, \(\vdash^h M : A\) then \(\vdash M : A\).

**Proof.** By induction on the derivation of \(\vdash^h M : A\).

If \(\vdash^h M : A\) is one of the axioms of \(A\), \(\Pi I, I1, K1\) or \(S1\), or is generated by (I) or (II), we have \(\vdash M : A\).

The (application) and (conversion) cases follow from the induction hypothesis.

The (subject reduction) and (type reduction) cases follow from the induction hypothesis and Lemma 3.6.

**Lemma 7.5.** In a HPTS corresponding to a supersorted PTS,

(i) If \((M : A) \in A \cup B\) then there is an \(s \in \mathcal{S}\) such that \((A : s) \in A \cup B\).

(ii) If \(\left(\lambda x_1 : A_1 \ldots \lambda x_{i-1} : A_{i-1} \cdot \Pi x_i : A_i, B\right) : \left[\Pi x_1 : A_1 \ldots \Pi x_{i-1} : A_{i-1} \cdot s\right] \in B\), there is an \(s' \in \mathcal{S}\) such that \(\left(\lambda x_1 : A_1 \ldots \lambda x_i : A_i, B\right) : \left[\Pi x_1 : A_1 \ldots \Pi x_i : A_i, s'\right] \in B\).

**Proof.**

(i) If \(A \in \mathcal{S}\) this follows by supersortedness.

If \((M : A) \in B\) and \(A \notin \mathcal{S}\), we have \(\vdash M : A\) by Theorem 7.4 and \(\vdash A : s\), for some \(s \in \mathcal{S}\), by Lemma 3.5.

Hence \((A : s) \in B\) by (I).

(ii) If \(\left(\lambda x_1 : A_1 \ldots \lambda x_{i-1} : A_{i-1} \cdot \Pi x_i : A_i, B\right) : \left[\Pi x_1 : A_1 \ldots \Pi x_{i-1} : A_{i-1} \cdot s\right] \in B\), by Theorem 7.4 and Lemma 3.4(iv) and (iii) we have, for some \(s' \in \mathcal{S}\),

\[
x_1 : A_1 \ldots x_i : A_i \vdash B : s'.
\]

(abstraction) and (II) then give the result.

We also need an extension of \(\lambda X^h\) that allows hypotheses.

**Definition 7.6** \((\lambda X^{h+})\). If \(\lambda X\) is a PTS, \(\lambda X^{h+}\) has all the postulates of \(\lambda X^h\), also with nonempty contexts, and the (start) and (weakening) rules of \(\lambda X\).

**Lemma 7.7.** \(\vdash^{h+} M : A \iff \vdash^h M : A\).

**Proof.** Immediate because in a derivation of \(\vdash^{h+} M : A\) no (start) or (weakening) rule can be used. No nonempty context can be emptied in \(\lambda X^{h+}\).
The extra axioms of $\mathcal{B}$ generated by (I) we will need in the proof of the Correctness of Types Lemma for $\lambda X^{h+}$ (if $\Gamma \vdash^{h+} M : A$ then $\Gamma \vdash^{h+} A : s$ for some $s$).

Those generated by (II) we need in the proof of (abstraction) to show that, if we have $\Gamma \vdash^{h+} (\Pi x : C.D) : s_3$, we also have for $(s_1, s_2, s_3) \in \mathcal{R}$, $\Gamma \vdash^{h+} C : s_1$ and $\Gamma \vdash^{h+} (\lambda x : C.D) : (\Pi x : C.s_2)$, where the derivation of the latter is no longer than the derivation of $\Gamma \vdash^{h+} (\Pi x : C.D) : s_3$. The “no longer than” is needed for proof by induction to work.

Many of the axioms are, in a sense, superfluous. We can for example, prove axioms $\Pi 4, \Pi 8$ and $\Pi 11$ (below) from Axiom $K 1$ and Axiom $\Pi 5$ from Axioms $\Pi 1$ and $\Pi 4$. However, using fewer axioms can mean that the derivation of a $\Gamma \vdash^{h+} (\lambda x : C.D) : (\Pi x : C.s_2)$ is longer than that of $\Gamma \vdash^{h+} (\Pi x : C.D) : s_3$.

To illustrate that the axioms, generated by (I) and (II) above, form finite sets, we list all the ones generated by Axiom $\Pi 1(s_i')$ below is such that $(s_i : s_i') \in \mathcal{A})$. There are another six I axioms, another sixteen $K$ axioms and twenty-nine more $S$ axioms.

$\Pi 2 \quad \vdash^h [\Pi u : s_1, \Pi v : (\Pi x : u.s_2).s_3] : s_4.
\Pi 3 \quad \vdash^h [\lambda x : s_1, \Pi v : (\Pi x : u.s_2).s_3] : [\Pi u : s_1.s_4].
\Pi 4 \quad \vdash^h [\lambda x : s_1.s_2] : [\Pi u : s_1.s_2'].
\Pi 5 \quad \vdash^h [\Pi u : s_1.s_2] : s_3.
\Pi 6 \quad \vdash^h [\lambda x : s_1, \lambda v : (\Pi x : u.s_2), \lambda x : u.vx] : [\Pi u : s_1, \Pi v : (\Pi x : u.s_2).\Pi x : u.s_2].
\Pi 7 \quad \vdash^h [\Pi u : s_1, \Pi v : (\Pi x : u.s_2).\Pi x : u.s_3] : s_4.
\Pi 8 \quad \vdash^h [\lambda x : s_1, \lambda v : (\Pi x : u.s_2).s_3] : [\Pi u : s_1, \Pi v : (\Pi x : u.s_2).s_3'],
\Pi 9 \quad \vdash^h [\lambda x : s_1, \Pi v : (\Pi x : u.s_2).\Pi x : u.s_3] : [\Pi u : s_1.s_4].
\Pi 10 \quad \vdash^h [\lambda x : s_1, \lambda v : (\Pi x : u.s_2).\Pi x : u.s_3] : [\Pi u : s_1, \Pi v : (\Pi x : u.s_2).s_4].
\Pi 11 \quad \vdash^h [\lambda x : s_1, \lambda v : (\Pi x : u.s_2), \lambda x : u.s_3] : [\Pi u : s_1, \Pi v : (\Pi x : u.s_2).\Pi x : u.s_3'].

The axiom required by (I) for $\Pi 1, \Pi 8$ and $\Pi 10$ is $\Pi 2$, for $\Pi 3, \Pi 4$ and $\Pi 9, \Pi 5$, for $\Pi 11$, $\Pi 7$ and for $\Pi 6$ the instance of $\Pi 7$ where $s_2 = s_3$. The axiom required by (II) for $\Pi 1$ is $\Pi 6$, for $\Pi 2$ is $\Pi 3$, for $\Pi 3$ is $\Pi 8$, for $\Pi 5$ is $\Pi 4$, for $\Pi 7$ is $\Pi 9$, for $\Pi 9$ is $\Pi 10$ and for $\Pi 10$ is $\Pi 11$.

Each axiom is an scheme in the sense that it is an axiom for all $s_1, s_2, \ldots$ for which it is provable in $\lambda X$. Thus most axioms (not $\Pi 6$) have some restrictions, other than $s_i : s'_i \in \mathcal{A}$, for example $(s_1, s'_2, s_3), (s_5, s'_3, s_4) \in \mathcal{R}$ in $\Pi 3$. Some of these restrictions will appear in (the proofs of) some of the lemmas for $\lambda X^{h+}$ below.

We will show later that in $\lambda X^{h+}$, for a suitable $\lambda X$, (product) and (abstraction) are admissible and that the theorems of $\lambda X^{h+}$ are exactly those of $\lambda X^h$ and $\lambda X$.

8. THE CORRECTNESS OF TYPES LEMMAS FOR $\lambda X^{h+}$

To state and prove some preliminary lemmas we need some definitions.

Definition 8.1 (major premise chain). A major premise chain (mpc) in a derivation is a sequence of judgements starting with one formed by a (start) rule or an axiom. The remaining judgements of the chain are obtained by (weakening), (application) or (conversion), with the previous judgement as major premise, or by (subject reduction) or (type reduction). The minor premises in (weakening), (application) and (conversion) rules for which the major premises are in an mpc, will be called the minor premises attached to the mpc.

The final judgement of an mpc that is not a proper part of a larger mpc, must be the final judgement in a derivation, a judgement that is the premise for a (start) rule or the minor premise in a (weakening), (application) or (conversion) rule.
Any derivation is therefore made up of linked mpcs.

**Definition 8.2.** An mpc is said to be *long* if it starts with an axiom of the form
\[ \vdash^{\text{h}+} [\lambda x_1:A_1 \ldots \lambda x_n:A_n.N] : [\Pi x_1:A_1 \ldots \Pi x_n:A_n.A_{n+1}] \]  
(8.1)
where \( n > 0 \), \( N \) is one of \( x_1, \ldots, x_n \) or is formed by application from (some of) \( x_1, \ldots, x_n \) and the mpc has at least \( n \) (application) steps and (subject reduction) steps that reduce all of the \( n \lambda x_i \) redexes. An mpc is *short* otherwise.

A derivation is *short* if it has no long mpcs and *long* otherwise.

**Definition 8.3** (Application Length - alength). The *application length* or *alength* of a derivation is its number of (application) steps, where steps in identical minor premises in the derivation, are counted only once.

A derivation of lesser alength than another will be called *shorter*, one of greater alength *longer*.

**Note.** One derivation of a judgement may be shorter (in length) than another without being short.

**Lemma 8.4.** If the final mpc in a derivation of
\[ \Gamma \vdash^{\text{h}+} M : A. \]
(8.2)
is long, it starts with an axiom of the form \([8.1]\) and the (subject reduction) step that reduces the \( \lambda x_n \) redex comes directly after the \( n \)th (application) step, then that derivation of \([8.2]\) can be replaced by an *shorter* one.

**Proof.** This has to be proved for each of the axioms of \( \mathcal{B} \) that is of this form. We will prove it for Axiom S8, below, the proofs for other axioms are similar.

\[ \text{S8} \quad [\lambda y_1:s_q.\lambda y_2:(\Pi x:y_1.s_r).\lambda y_3:(\Pi x:y_1.\Pi y:y_2.x.y).\lambda y_4:(\Pi x:y_1.\Pi y:y_2.x.y).\lambda y_5:(\Pi x:y_1.\Pi y:y_2.x.y).\lambda y_6:(\Pi x:y_1.\Pi y:y_2.x.y).\lambda y_7:(\Pi x:y_1.\Pi y:y_2.x.y).\lambda y_8:(\Pi x:y_1.\Pi y:y_2.x.y).] \]

Let the minor premises in the six (application) steps involving \( \Pi y_1 \) to \( \Pi y_6 \) in the long derivation of \([8.2]\) be, for \( 1 \leq i \leq 6 \):
\[ \Gamma_i \vdash^{\text{h}+} Y_i : E_i \]
where \( E_1 = \beta s_q, E_2 = \beta \Pi x:Y_1.s_r, E_3 = \beta \Pi x:Y_1.\Pi y:Y_2.x.s_t, E_4 = \beta (\Pi x:Y_1.\Pi y:Y_2.x.Y_3.y), E_5 = \beta \Pi x:Y_1.\Pi y:Y_2.x, E_6 = \beta \Pi x:Y_1.\Pi y:Y_2.x.s_t \) and \( Y_3Y_6(Y_5Y_6) \rightarrow^\beta M \).

Then for some \( Y_i^*, Y_1 \rightarrow^\beta Y_i^* \) and \( E_6 \rightarrow^\beta Y_i^* \) and for some \( R[X], Y_2x \rightarrow^\beta R[X], E_3 \rightarrow^\beta \Pi x:Y_i^*.\Pi y:R[x].s_t \) and \( E_5 \rightarrow^\beta \Pi x:Y_i^*.R[x] \).

Note that as contexts can only grow, each \( \Gamma_i \) for \( 1 \leq i < 6 \) is an initial segment of \( \Gamma_{i+1} \).

Now by (weakening), (subject reduction), (type reduction) and just three (application) steps we get from three of these minor premises:
\[ \Gamma_6 \vdash^{\text{h}+} Y_3Y_6 : \Pi y:R[X].s_t, \]
\[ \Gamma_6 \vdash^{\text{h}+} Y_5Y_6 : R[X] \]
and so
\[ \Gamma_6 \vdash^{\text{h}+} Y_3Y_6(Y_5Y_6) : s_t \]
which, as $Y_3 Y_6 (Y_5 Y_6) \rightarrow \beta M$, gives \[S.2\].

We now have a new derivation of \[S.2\], which, given that any (application)s in the two uses of $\Gamma \vdash Y_6 : E_6$ are counted only once, has fewer (application)s, and so is shorter than, the old derivation of \[S.2\].

**Lemma 8.5** (Shortness Lemma for HPTS$^+$). *Every valid judgement in a HPTS$^+$ has a short derivation.*

**Proof.** We prove this by showing that for every long derivation there is an ashorter derivation of the same judgement.

Assume that the following is the part of a long mpc, in a long derivation, up to the $\lambda x_n$ reduction, together with the minor premises used in the n (application) steps.

\[
\vdash^{h+} T_1 : \Pi x_1 : B_0, C_0
\]

\[
\vdash^{h+} T_1 : \Pi x_1 : B_1, C_1 \quad \vdash^{h+} X_1 : B_1
\]

\[
\vdash^{h+} T_1 X_1 : C_1[x_1 := X_1]
\]

\[
\vdash^{h+} T_2 : \Pi x_2 : B_2, C_2 \quad \vdash^{h+} X_2 : B_2
\]

\[
\vdash^{h+} T_2 X_2 : C_2[x_2 := X_2]
\]

\[
\vdash^{h+} T_n : \Pi x_n : B_n, C_n \quad \vdash^{h+} X_n : B_n
\]

\[
\vdash^{h+} T_n X_n : C_n[x_n := X_n]
\]

\[
\vdash^{h+} (\lambda x_n : A'_n, N') X'_n Y_1 \ldots Y_k : D
\]

\[
\vdash^{h+} N'[x_n := X'_n] Y_1 \ldots Y_k : D
\]

Here $\vdash^{h+} T_1 : \Pi x_1 : B_0, C_0$ is an axiom of the form \[S.1\] with $N$ made up of (some of) $x_1, \ldots, x_n, T_n \rightarrow \beta \lambda x_n : A'_n, N'$ and $X_n \rightarrow \beta X'_n$. The first, second and nth of the $n$ or more (application)s and the (subject reduction) contracting the $\lambda x_n$ redex are explicitly shown. The steps after the nth (application) only alter $T_n$ by reducing it, so steps can be permuted so that the $\lambda x_n$ reduction takes place straight after the nth (application) step as follows:

\[
\vdash^{h+} T_n : \Pi x_n : B_n, C_n
\]

\[
\vdash^{h+} \lambda x_n : A'_n, N' : \Pi x_n : B_n, C_n
\]

\[
\vdash^{h+} (\lambda x_n : A'_n, N') X_n : C_n[x_n := X_n]
\]

\[
\vdash^{h+} N'[x_n := X_n] : C_n[x_n := X_n]
\]

\[
\vdash^{h+} N'[x_n := X'_n] Y_1 \ldots Y_k : D
\]
This new derivation is no longer than the original, but the part up to $\Gamma_n \vdash^h N'[x_n := X'_n] : C_n[x_n := X_n]$ is long and can be replaced, by Lemma 8.4, by a shorter derivation, so the whole derivation becomes shorter. (If the derivation had identical mpcs to the above, which were all minor premises in the same mpc, all would have to be altered as above to ensure that the new derivation is not longer than the old.)

In the remaining lemmas and theorems we use a different measure of length of a derivation, where “similar” subderivations are counted only once.

**Definition 8.6 (Similar).** Two derivations are said to be similar if they are identical or one, in its final mpc, starts with an axiom of $B$ of the form \((8.1)\), and the other differs only in that its final mpc starts with an axiom of $B$ generated from the other by one or more applications of (II).

We now define:

**Definition 8.7 (Similarity Length - slength).** The similarity length (or slength) of a derivation is given by:

(i) the number of (application) steps,
(ii) the number of (conversion), (start) and (weakening) steps.

Similar derivations ending in the two premises of a (weakening) step, are counted only once.

A derivation of lesser slength than another will be said to be ssborter and one of greater slength as slonger.

**Lemma 8.8.** Given, for $s' \in S$, a short derivation of:

$$\Gamma \vdash^h \Pi x : B.C : s',$$

there is, for some $s \in S$, a derivation, no longer or slonger than that of \((8.3)\), of

$$\Gamma \vdash^h \lambda x : B.C : \Pi x : B.s.$$  \hspace{1cm} (8.4)

**Proof.** Consider the first judgement in the final mpc in a short derivation of \((8.3)\). This cannot be an axiom of $A$ or be formed by a (start) rule, so it is an axiom of $B$ of the form \((8.1)\), where $N \equiv \Pi x : B'.C'$ and $A_{n+1} \equiv s'$.

If in this mpc we replace this axiom by the one generated from it by (II), then using exactly the same steps and minor premises we obtain a derivation of \((8.4)\) of the same length.

In this final mpc there are no (weakening) steps in which the premises are similar, until perhaps after the last (application) step, as, until then, no type can be in $S$. If, at that stage, \((8.3)\) is formed by one or more (weakening) steps (and perhaps (subject reduction)) from $\Gamma^- \vdash^h \Pi x : B^0.C^0 : s'$ and similar minor premises such as $\Gamma^- \vdash^h D : s'$, these are counted only once each in the slength. In the derivation obtained by changing the axiom, the above derivations remain similar and so the slength of the derivation remains the same.

**Lemma 8.9 (Correctness of Types for HPTS+).** If $\lambda X$ is supersorted and

$$\Gamma \vdash^h M : A,$$  \hspace{1cm} (8.5)

then, for some $s \in S$, $A \equiv s$ or there is a short derivation, of slength no more than that of a short derivation of \((8.5)\), of

$$\Gamma \vdash^h A : s.$$  \hspace{1cm} (8.6)
Proof. By induction on the number \( k \), of judgements in the final mpc of a short derivation of \( \Gamma \vdash \vdash h + M : A \), where \( A \not\in S \).

If \( k = 1 \) and \( (8.5) \) comes by a (start) rule from

\[
\Gamma - \vdash h + A : s,
\]

where \( M \equiv x \) and \( \Gamma \equiv \Gamma - , x : A \), \( (8.6) \) comes from two copies of \( (8.7) \) and (weakening). The two derivations of \( (8.7) \) are counted only once, so this derivation of \( (8.6) \) is no slonger than that of \( (8.5) \).

If \( (8.5) \) is an axiom we have \( (8.6) \) by (I) or by supersortedness.

We now assume \( k \geq 2 \).

If \( (8.5) \) comes from \( \Gamma' \vdash h + M : A \) and \( \Gamma' \vdash h + B : s' \), by (weakening), where \( s' \in S \), \( A \not\in S \) and \( \Gamma = \Gamma' \), \( x : B \), these derivations are both counted in the slength of the derivation of \( (8.5) \). We have, by the induction hypothesis, \( \Gamma' \vdash h + A : s \), by a derivation no slonger than that of \( (8.5) \). We now assume \( k \geq 2 \).

If \( (8.5) \) comes from \( \Gamma \vdash h + N : A \), by (subject reduction), we have \( (8.6) \) by a derivation no slonger than that of \( (8.5) \).

If \( (8.5) \) comes from \( \Gamma \vdash h + M : B \), by (type reduction), we have \( \Gamma \vdash h + B : s \) by the induction hypothesis and \( (8.6) \) by (subject reduction), by a derivation no slonger than that of \( (8.5) \).

If \( (8.5) \) comes from \( \Gamma \vdash h + M : B \), by (conversion), we have \( (8.6) \) by a derivation sshorter than that of \( (8.5) \).

If \( (8.5) \) comes from \( \Gamma \vdash h + P : \Pi x : B.C \) and \( \Gamma \vdash h + Q : B \), where \( M \equiv PQ \) and \( A \equiv C[x := Q] \), by (application), we have by the induction hypothesis, \( \Gamma \vdash h + \Pi x : B.C : s' \) for some \( s' \in S \), by a derivation no slonger than that of \( (8.5) \). Then by Lemma \( 8.8 \) we have \( \Gamma \vdash h + \lambda x : B.C : \Pi x : B.s \), for some \( s \in S \) by a derivation no slonger than that of \( (8.5) \). Then by (application) using \( \Gamma \vdash h + Q : B \) we have \( (8.6) \) by a derivation no slonger than that of \( (8.5) \).

Lemma 8.10 (Start Lemma for HPTS\(^+\)). If

\[
\Gamma, x : A \vdash h + M : B
\]

then, for some \( s \in S \),

\[
\Gamma \vdash h + A : s.
\]

Proof. By an easy induction on the derivation of \( (8.8) \). \( \square \)

9. The Equivalence Results

Lemma 9.1. If \( \lambda X \) is supersorted, (abstraction) is admissible in \( \lambda X^{h+} \).

Proof. If \( \lambda X \) is supersorted we prove that if

\[
\Gamma, x : A \vdash h + M : B
\]

then

\[
\Gamma \vdash h + (\lambda x : A.M) : (\Pi x : A.B)
\]

by induction on the slength of a short derivation of \( (9.1) \).
Case 1. \((9.1)\) comes by (start) (and (type reduction)) from

\[ \Gamma \vdash^{h+} A : s \]

where \(M \equiv x\) and \(A \rightarrow B\).

By Axiom \(\Pi_1\) and (application) (and (type reduction)) we have \((9.2)\).

Case 2. \((9.1)\) comes by (weakening) (and reduction) from

\[ \Gamma \vdash^{h+} M' : B' \quad \text{and} \quad \Gamma \vdash^{h+} A : s_2 \]

then by the Correctness of Types Lemma (Lemma 8.9) or supersortedness, for some \(s_1\).

\[ \Gamma \vdash^{h+} B' : s_1 \]

and \((9.2)\) follows after three (applications) applied to Axiom \(K_1\) (and reduction).

Case 3. \((9.1)\) comes by (conversion) (and reduction) from

\[ \Gamma, x : A \vdash^{h+} M : C \quad \Gamma, x : A \vdash^{h+} B' : s_2 \quad \text{and} \quad C = \beta B' \rightarrow B. \]

By the induction hypothesis and (subject reduction) we have:

\[ \Gamma \vdash^{h+} (\lambda x : A.M) : (\Pi x : A.C) \]  

and

\[ \Gamma \vdash^{h+} (\lambda x : A.B) : (\Pi x : A.s_2) \]

where \(\Pi x : A.C =_\beta \Pi x : A.B\).

We have by Lemma 8.9 applied to \((9.1)\), for some \(s_1\),

\[ \Gamma \vdash^{h+} A : s_1 \]

and, by supersortedness \((s_1, s_2, s_3) \in R\) for some \(s_3\), so by Axiom \(\Pi_1\) and (subject reduction),

\[ \Gamma \vdash^{h+} (\Pi x : A.B) : s_3, \]

hence by \((9.3)\) and (conversion) we have \((9.2)\).

Case 4. \((9.1)\) comes by (application) (and reduction) from

\[ \Gamma, x : A \vdash^{h+} P : (\Pi y : C.D) \]  

and

\[ \Gamma, x : A \vdash^{h+} Q : C \]  

where \(PQ \rightarrow M\) and \(D[y := Q] \rightarrow B\).

By the Correctness of Types lemma we have for some \(s_4 \in S\), by a derivation no longer than that of \((9.4)\):

\[ \Gamma, x : A \vdash^{h+} (\Pi y : C.D) : s_4 \]

now by Lemma 8.8 we have for some \(s_3 \in S\), by a derivation no longer than that of \((9.4)\), and so shorter than that of \((9.4)\):

\[ \Gamma, x : A \vdash^{h+} (\lambda y : C.D) : (\Pi y : C.s_3) \]

Now by the induction hypothesis applied to \((9.4)\), \((9.5)\) and \((9.7)\) we have:

\[ \Gamma \vdash^{h+} (\lambda x : A.P) : (\Pi x : A.\Pi y : C.D) \]

\[ \Gamma \vdash^{h+} (\lambda x : A.Q) : (\Pi x : A.C) \]

\[ \Gamma \vdash^{h+} (\lambda x : A.\lambda y : C.D) : (\Pi x : A.\Pi y : C.s_3) \]
also by the Correctness of Types Lemma applied to (9.9) we have for some \( s_4 \in S \)
\[
\Gamma \vdash^{h^+} (\Pi x : A.C) : s_4 
\]
and by Lemma 8.8 for some \( s_2 \in S \)
\[
\Gamma \vdash^{h^+} (\lambda x : A.C) : (\Pi x : A.s_2) \tag{9.11} 
\]
now by Axiom S1, \( \Gamma \vdash^{h^+} A : s_1 \) (obtained as in Case 3) \( \tag{9.11}, \tag{9.10}, \tag{9.8}, \tag{9.9} \) and five (application)s, (subject reduction) and (type reduction) give \( \tag{9.2} \). (Note that in Axiom S1 \( s_1, s_2 \) and \( s_3 \) (here \( s_1, s_5 \) and \( s_2 \)) can be arbitrarily chosen in a supersorted PTS).

**Lemma 9.2.** If \( \lambda X \) is supersorted (product) is admissible in \( \lambda X^{h^+} \).

**Proof.** If \( \Gamma \vdash^{h^+} A : s_1, \Gamma, x : A \vdash^{h^+} B : s_2 \) and \((s_1, s_2, s_3) \in R\) by Lemma 9.1,
\[
\Gamma \vdash^{h^+} \lambda x : A.B : \Pi x : A.s_2 
\]
so by Axiom III, (application) and (subject reduction) we have
\[
\Gamma \vdash \Pi x : A.B : s_3. \tag{9.2} 
\]

Lemmas 9.1 and 9.2 show that a theorem that can be proved in \( \lambda X^{h^+} \), using hypotheses, (abstraction) and (product), can also be proved in \( \lambda X^h \). So:

**Theorem 9.3.** If \( \lambda X \) is supersorted it is equivalent to \( \lambda X^{h^+} \) in that they have the same valid judgements.

**Proof.** By Theorem 7.4 \( \lambda X^h \) is a subsystem of \( \lambda X \). The additional rules of \( \lambda X^{h^+} \) are rules of \( \lambda X \), so \( \lambda X^{h^+} \) is a subsystem of \( \lambda X \). The extra rules of \( \lambda X \) have been shown to be admissible in \( \lambda X^{h^+} \) in Lemmas 9.1 and 9.2 so \( \lambda X^{h^+} \) and \( \lambda X \) have the same valid judgements.

**Theorem 9.4.** If \( \lambda X \) is supersorted \( \lambda X \) and \( \lambda X^{h^+} \) are equivalent in that they have the same theorems.

**Proof.** It follows from Theorem 9.3 that \( \lambda X \) and \( \lambda X^{h^+} \) have the same valid judgements with empty contexts i.e. theorems and so by Lemma 7.7 that \( \lambda X \) and \( \lambda X^h \) have the same theorems.

10. **Axioms I, K, S and \( \Pi \) as Types**

Axioms I1, K1 and S1 can be rewritten in terms of type free combinators (allowing \( \eta \)-reduction) as:

**Axiom I1** \( \vdash KI : (\Pi x : s_1, \Pi y : x.x) \).

**Axiom K1** \( \vdash KK : (\Pi x : s_1, \Pi y : s_2, \Pi z : y.Pi u : x.y) \).

**Axiom S1** \( \vdash KKS : [\Pi u : s_1, \Pi v : (\Pi x : u.s_2).Pi t : (\Pi x : u.Pi y : vx.s_3)].Pi w : (\Pi x : u.Pi y : vx.txy).Pi z : (\Pi x : u.vx).Pi z : (\Pi x : u.tx(zx)) \).

These give the standard types of the combinators (writing \( A \rightarrow B \) for \( \Pi x : A.B \) when \( x \notin FV(B) \)):

\[
\vdash A : s_1 \Rightarrow \vdash I : A \rightarrow A \\
\vdash A : s_1, \vdash B : s_2 \Rightarrow \vdash K : B \rightarrow A \rightarrow B \\
\vdash A : s_1, \vdash B : A \rightarrow s_2, \vdash C : (\Pi x : A.Pi y : Bx.s_3) \Rightarrow \vdash S : Pi w : (\Pi x : A.Pi y : Bx.Cxy).Pi z : (\Pi x : A.Bx).Pi x : A.Cx(zx) 
\]
or, as a special case
\[ \vdash A : s_1, \vdash B' : s_2, \vdash C' : A \to B' \to s_3 \Rightarrow \vdash S : (A \to B' \to C') \to (A \to B') \to (A \to C') \]
If \( \Pi x:U . V x \), where \( x \notin FV(UV) \), were represented as \( GUV \) (as it is in ICL), Axiom III1 represents the type for \( G \) (or \( \lambda uv . \Pi x : u . s_2 \cdot s_3 \)):
\[ \vdash G : (\Pi u : s_1 . (\Pi v : (\Pi x : u . s_2) . s_3)) \quad \text{or} \quad \vdash G : (\Pi u : s_1 . (u \to s_2) \to s_3). \]

11. Identifying \( \lambda \) and \( \Pi \)

In the de Bruijn AUTOMATH systems \( \Pi \) and \( \lambda \) are usually identified. Kameraddine has studied the effect of allowing \( \beta \)-reductions in the (former) \( \Pi \) terms in [5]. Doing this Axiom I1 becomes:
\[ \vdash KI : (\lambda x : s_1 \cdot \lambda y : x . x) \]
and similarly for the other axioms. If we write the type in terms of combinators we can get (depending on the algorithm)
\[ \vdash KI : S(KK)I \quad \text{or} \quad \vdash KI : K. \]

12. Conclusion

We have shown that PTSs come in at least three categories: those satisfying \((s)\) and \((s\ldots s)\) that have no equivalent HPTS, those satisfying \((s_1 \ldots s_n)\) that have only a trivial equivalent HPTS and supersorted PTSs, such as \( \lambda \)Coq, that have a nontrivial equivalent HPTS. The standard PTSs from the literature that we considered all fit into these categories.
