e-mail address: mateus.oliveira@uib.no

Abstract. Let CMSO denote the counting monadic second-order logic of graphs. We give a constructive proof that for some computable function \( f \), there is an algorithm \( A \) that takes as input a CMSO sentence \( \varphi \), a positive integer \( t \), and a connected graph \( G \) of maximum degree at most \( \Delta \), and determines, in time \( f(|\varphi|,t) \cdot 2^{O(\Delta \cdot t)} \cdot |G|^{O(1)} \), whether \( G \) has a supergraph \( G' \) of treewidth at most \( t \) such that \( G' \models \varphi \).

The algorithmic metatheorem described above sheds new light on certain unresolved questions within the framework of graph completion algorithms. In particular, using this metatheorem, we provide an explicit algorithm that determines, in time \( f(d) \cdot 2^{O(\Delta \cdot d)} \cdot |G|^{O(d)} \), whether a connected graph of maximum degree \( \Delta \) has a planar supergraph of diameter at most \( d \). Additionally, we show that for each fixed \( k \), the problem of determining whether \( G \) has an \( k \)-outerplanar supergraph of diameter at most \( d \) is strongly uniformly fixed parameter tractable with respect to the parameter \( d \).

This result can be generalized in two directions. First, the diameter parameter can be replaced by any contraction-closed effectively CMSO-definable parameter \( \mathbf{p} \). Examples of such parameters are vertex-cover number, dominating number, and many other contraction-bidimensional parameters. In the second direction, the planarity requirement can be relaxed to bounded genus, and more generally, to bounded local treewidth.

1. Introduction

A parameterized problem \( \mathcal{L} \subseteq \Sigma^* \times \mathbb{N} \) is said to be fixed parameter tractable (FPT) if there exists a function \( f : \mathbb{N} \to \mathbb{N} \) such that for each \( (x, k) \in \Sigma^* \times \mathbb{N} \), one can decide whether \( (x, k) \in \mathcal{L} \) in time \( f(k) \cdot |x|^{O(1)} \), where \( |x| \) is the size of \( x \) \cite{DF99}. Using non-constructive methods derived from Robertson and Seymour’s graph minor theory, one can show that certain problems can be solved in time \( f(k) \cdot \tilde{|x|}^{O(1)} \) for some function \( f : \mathbb{N} \to \mathbb{N} \). The caveat is that the function \( f \) arising from these non-constructive methods is often not known to be computable. Interestingly, for some problems it is not even clear how to obtain algorithms running in time \( f_1(k) \cdot |x|^{f_2(k)} \) for some computable functions \( f_1 \) and \( f_2 \). In this work we will use techniques from automata theory and structural graph theory to provide constructive FPT and XP algorithms for problems for which only non-constructive parameterized algorithms were known.

Key words and phrases: CMSO Logic, Algorithmic Metatheorems, Graph Completion, Bidimensionality.

A preliminary version of this work appeared at the 26th EACSL Annual Conference on Computer Science Logic, CSL 2017 \cite{dOO17}. 
The counting monadic second-order logic of graphs (CMSO) extends first order logic by allowing quantifications over sets of vertices and sets of edges, and by introducing the notion of modular counting predicates. This logic is expressive enough to define several interesting graph properties, such as Hamiltonicity, 3-colorability, connectivity, planarity, fixed genus, minor embeddability, etc. Additionally, when restricted to graphs of constant treewidth, CMSO logic is able to define precisely those properties that are recognizable by finite state tree-automata operating on encodings of tree-decompositions, or equivalently, those properties that can be described by equivalence relations with finite index [Cou90, AF93, BP16, BP17].

The expressiveness of CMSO logic has had a great impact in algorithmic theory due to Courcelle’s model-checking theorem [Cou90]. This theorem states that for some computable function \( f : \mathbb{N}^2 \rightarrow \mathbb{N} \), one can determine in time \( f(|\varphi|, t) \cdot |G| \) whether a given graph \( G \) of treewidth at most \( t \) satisfies a given CMSO sentence \( \varphi \). As a consequence of Courcelle’s theorem, many combinatorial problems, such as Hamiltonicity or 3-colorability, which are NP-hard on general graphs, can be solved in linear time on graphs of constant treewidth. In this work we will consider a class problems on graphs of constant treewidth which cannot be directly addressed via Courcelle’s theorem, either because it is not clear how to formulate the set of positive instances of such a problem as a CMSO-definable set, or because although the set of positive instances is CMSO-definable, it is not clear how to explicitly construct a CMSO sentence \( \varphi \) defining such set. For instance, sets of graphs that are closed under minors very often fall in the second category due to Robertson and Seymour’s graph minor theorem.

1.1. Main Result. Let \( \varphi \) be a CMSO sentence, and \( t \) be a positive integer. We say that a graph \( G' \) is a \((\varphi, t)\)-supergraph of a graph \( G \) if the following conditions are satisfied: \( G' \) satisfies \( \varphi \), \( G' \) has treewidth at most \( t \), and \( G' \) is a supergraph of \( G \) (possibly containing more vertices than \( G \)).

In our main result, Theorem 6.2, we devise an algorithm \( \mathcal{A} \) that takes as input a CMSO sentence \( \varphi \), a positive integer \( t \), and a connected graph \( G \) of maximum degree \( \Delta \), and determines in time \( f(|\varphi|, t) \cdot 2^{O(\Delta \cdot t)} \cdot |G|^{O(t)} \) whether \( G \) has a \((\varphi, t)\)-supergraph. We note that our algorithm determines the existence of such a \((\varphi, t)\)-supergraph \( G' \) without the need of necessarily constructing \( G' \). Therefore, no bound on the size of a candidate supergraph \( G' \) is imposed. Note that a priori even the fact that the problem is decidable is not clear.

In the next three sub-sections we show how Theorem 6.2 can be used to provide partial solutions to certain long-standing open problems in parameterized complexity theory.

1.2. Planar Diameter Improvement. In the PLANAR DIAMETER IMPROVEMENT problem (PDI), we are given a graph \( G \), and a positive integer \( d \), and the goal is to determine whether \( G \) has a planar supergraph \( G' \) of diameter at most \( d \). Note that the set of YES instances for the PDI problem is closed under minors. In other words, if \( G \) has a planar supergraph of diameter at most \( d \), then any minor \( H \) of \( G \) also has such a supergraph. Therefore, using non-constructive arguments from Robertson and Seymour’s graph minor theory [RS95, RS04] in conjunction with the fact planar graphs of constant diameter have constant treewidth, one can show that for each fixed \( d \), there exists an algorithm \( \mathcal{A}_d \) which determines in linear time whether a given \( G \) has diameter at most \( d \). The problem is that the non-constructive

---

1.\(|G|\) denotes the number of vertices in \( G \), and \(|\varphi|\), the number of symbols in \( \varphi \).
techniques mentioned above provide us with no clue about what the algorithm \(A_d\) actually is. This problem can be partially remedied using a technique called effectivization by self-reduction introduced by Fellows and Langston [FL89, DF99]. Using this technique one can show that for some function \(f : \mathbb{N} \rightarrow \mathbb{N}\), there exists a single algorithm \(A\) which takes a graph \(G\) and a positive integer \(d\) as input, and determines in time \(f(d) \cdot |G|^{O(1)}\) whether \(G\) has a planar supergraph of diameter at most \(d\). The caveat is that the function \(f : \mathbb{N} \rightarrow \mathbb{N}\) bounding the influence of the parameter \(d\) in the running time of the algorithm mentioned above is not known to be computable.

Obtaining a fixed parameter tractability result for the PDI problem with a computable function \(f\) is a notorious and long-standing open problem in parameterized complexity theory [DF99, FD95, CFK+15]. Indeed, when it comes to explicit algorithms, the status of the PDI problem is much more elusive. As remarked in [CGK+15], even the problem of determining whether PDI can be solved in time \(f_1(d) \cdot |G|^{f_2(d)}\) for computable functions \(f_1, f_2 : \mathbb{N} \rightarrow \mathbb{N}\) is open.

Using Theorem 6.2 we provide an explicit algorithm that solves the PDI problem for connected graphs in time \(f(d) \cdot 2^{O(\Delta \cdot d)} \cdot |G|^{O(d)}\) where \(f : \mathbb{N} \rightarrow \mathbb{N}\) is a computable function, and \(\Delta\) is the maximum degree of \(G\). This result settles an open problem stated in [CGK+15] in the case in which the input graph is connected and has bounded (even logarithmic) degree. We note that our algorithm imposes no restriction on the degree of a prospective supergraph \(G'\).

1.3. \(k\)-Outerplanar Diameter Improvement. A graph is 1-outerplanar if it can be embedded in the plane in such a way that all vertices lie in the outer-face of the embedding. A graph is \(k\)-outerplanar if it can be embedded in the plane in such a way that that deleting all vertices in the outer-face of the embedding yields a \((k-1)\)-outerplanar graph. The \(k\)-outerplanar diameter improvement problem (\(k\)-OPDI) is the straightforward variant of PDI in which the completion is required to be \(k\)-outerplanar instead of planar. In [CGK+15] Cohen at al. devised an explicit polynomial time algorithm for the 1-OPDI problem. The complexity of the \(k\)-outerplanar diameter improvement problem was left open for \(k \geq 2\). Using Theorem 6.2 we show that the \(k\)-OPDI problem can be solved in time \(f(k,d) \cdot 2^{O(\Delta \cdot k)} \cdot |G|^{O(k)}\) where \(f : \mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}\) is a computable function. In other words, for each fixed \(k\), the \(k\)-outerplanar diameter improvement problem is strongly uniformly fixed parameter tractable with respect to the diameter parameter \(d\) for bounded degree connected input graphs.

1.4. Contraction-Closed Parameters. A graph parameter is a function \(p\) that associates a non-negative integer with each graph. We say that such a parameter is contraction-closed if \(p(G) \leq p(G')\) whenever \(G\) is a contraction of \(G'\). For instance, the diameter of a graph is clearly a contraction-closed parameter. We say that a graph parameter \(p\) is effectively CMSO-definable if there exists a computable function \(\alpha\), and an algorithm that takes a positive integer \(k\) as input and constructs a CMSO formula \(\varphi_k\) that is true on a graph \(G\) if and only if \(p(G) \leq k\).

The results described in the previous subsections can be generalized in two directions. First, the diameter parameter can be replaced by any effectively CMSO-definable contraction closed parameter that is unbounded on Gamma graphs. These graphs were defined in [FGT11] with the goal to provide a simplified exposition of the theory of contraction-bidimensionality.
In particular, many well studied parameters that arise often in bidimensionality theory satisfy the conditions listed above. Examples of such parameters are the sizes of a minimum vertex cover, feedback vertex set, maximal matching, dominating set, edge dominating set, connected dominating set etc. On the other direction, the planarity requirement can be relaxed to CMSO definable graph properties that exclude some apex graph as a minor. These properties are also known in the literature as bounded local-treewidth properties. For instance, embeddability on surfaces of genus $g$, for fixed $g$, is one of such properties.

1.5. Related Work. As mentioned above, given a CMSO sentence $\psi$ and a positive integer $t$, one can use Courcelle’s model checking theorem to determine in time $f(|\psi|, t) \cdot |G|^{O(1)}$ whether a given graph $G$ of treewidth at most $t$ satisfies $\psi$. Therefore, given a CMSO sentences $\varphi$ and a positive integer $t$, we may consider the following algorithmic approach to decide whether a given graph $G$ has a $(\varphi, t)$-supergraph: first, we construct a formula $\psi_{\varphi,t}$ which is true on a graph $G$ if there is a model $G'$ of $\varphi$ of treewidth at most $t$ such that $G$ is a subgraph of $G'$. In other words, $\psi_{\varphi,t}$ defines the subgraph closure of the set of models of $\varphi$ of treewidth at most $t$. Then, to determine whether $G$ has a $(\varphi, t)$-supergraph, it is enough to determine whether $G$ satisfies $\psi_{\varphi,t}$ using Courcelle’s model checking theorem.

Unfortunately, this approach cannot work in general. The problem is that there exist CMSO definable families of graphs whose subgraph closure is not CMSO definable. For instance, let $L = \{L_n\}_{n \in \mathbb{N}}$ be the family of ladder graphs, where $L_n$ is the ladder with $n$ steps. It is easy to see that $L$ is CMSO definable and every graph in $L$ has treewidth at most 2. Nevertheless, the subgraph closure of $L$ does not have finite index. Therefore, this subgraph closure is not CMSO definable, since CMSO definable classes of graphs of constant treewidth have finite index.

Interestingly, when the property defined by $\varphi$ is contraction closed, then the sentence $\psi_{\varphi,t}$ defines a minor-closed property $\mathcal{P}$ whose treewidth is bounded by $t$. Additionally, it follows from Robertson and Seymour graph minor theorem that each minor-closed property can be characterized by a finite set $\mathcal{M}$ of forbidden minors. Therefore, if we were able to enumerate the minors in $\mathcal{M}$ constructively, we would immediately obtain a constructive polynomial time algorithm for determining whether a given graph $G$ has a $(\varphi, t)$-supergraph. It is worth noting that Adler, Kreutzer and Grohe have shown that if a minor-free graph property $\mathcal{P}$ is MSO definable and has constant treewidth, then one can effectively enumerate the set of forbidden minors for $\mathcal{P}$ [AGK08]. In particular, by giving the sentence $\psi_{\varphi,t}$ as input to the algorithm in [AGK08] we would get a list of forbidden minors characterizing the set of graphs that have a $(\varphi, t)$-supergraph. Nevertheless, the problem with this approach is that it is not clear how the sentence $\psi_{\varphi,t}$ can be constructed from $\varphi$ and $t$.

In the embedded planar diameter improvement problem (EPDI), the input consists of a planar graph $G$ embedded in the plane, and a positive integer $d$. The goal is to determine whether one can add edges to the faces of this embedding in such a way that the resulting graph has diameter at most $d$. The difference between this problem and the PDI problem mentioned above is that in the EPDI problem, an embedding is given at the input, and edges must be added in such a way that the embedding is preserved, while in the PDI problem, no embedding is given at the input. Recently, it was shown in [LdOOS18] that EPDI for

---

2The vertices of $L_n$ are $a_1, \ldots, a_n$ and $b_1, \ldots, b_n$, and the edges are $\{a_i, b_i\}$ for $i \in [n]$, $\{a_i, a_{i+1}\}$ for $i \in [n-1]$, and $\{b_i, b_{i+1}\}$ for $i \in [n-1]$.
n-vertex graphs can be solved in time $2^{dO(d)}n^{O(d)}$, while the analogous embedded problem for k-outerplanar graphs can be solved in time $2^{dO(d)}n^{O(k)}$.

It is worth noting that the algorithms in [LdOOS18] heavily exploit the embedding of the input graph by viewing separators as nooses - simple closed curves in the plane that touch the graph only in the vertices (see e.g. [BMT03]). Additionally, it is currently unknown both whether PDI can be reduced to EPDI in XP time and whether EPDI can be reduced in XP time to PDI. Therefore it is not clear if the algorithm for EPDI can be used to provide a strongly uniform XP algorithm for PDI on general graphs. It is also worth noting that no hardness results for either PDI or EPDI are known. Indeed, determining whether either of these problems is NP-hard is also a long-standing open problem.

1.6. Proof Sketch And Organization of the Paper. In Section 2 we state some preliminary definitions. In Section 3 we define the notions of concrete bags, and concrete tree decompositions. Intuitively, a concrete tree-decomposition is an algebraic structure that represents a graph together with one of its tree decompositions. Using such structures we are able to define infinite families of graphs via tree-automata that accept infinite sets of tree decompositions. In particular, Courcelle’s theorem can be transposed to this setting. More precisely, there is a computable function $f$ such that for each CMSO sentence $\varphi$ and each $t \in \mathbb{N}$, one can construct in time $f(|\varphi|, t)$ a tree automaton $A(\varphi, t)$ which accepts precisely those concrete tree decompositions of width at most $t$ that give rise to graphs satisfying $\varphi$ (Theorem 3.3).

In Section 4 we define the notion of sub-decomposition of a concrete tree decomposition. Intuitively, if a concrete tree decomposition $T$ represents a graph $G$, then a sub-decomposition of $T$ represents a sub-graph of $G$. We show that given a tree-automaton $A$ accepting a set $\mathcal{L}(A)$ of concrete tree decompositions, one can construct a tree automaton $\text{Sub}(A)$ which accepts precisely those sub-decompositions of concrete tree decompositions in $\mathcal{L}(A)$ (Theorem 4.2).

In Section 5, we introduce the main technical tool of this work. More specifically, we show that for each connected graph $G$ of maximum degree $\Delta$, one can construct in time $2^{O(\Delta \cdot t)} \cdot |G|^{O(t)}$ a tree-automaton $A(G, t)$ whose language $\mathcal{L}(A(G, t))$ consists precisely of those concrete tree decompositions of width at most $t$ that give rise to $G$ (Theorem 5.5).

In Section 6 we argue that the problem of determining whether $G$ has a supergraph of treewidth at most $t$ satisfying $\varphi$ is equivalent to determining whether the intersection of $\mathcal{L}(A(G, t + 1))$ with $\mathcal{L}(\text{Sub}(A(\varphi, t + 1)))$ is non-empty. By combining Theorems 3.3, 4.2 and 5.5, we infer that this problem can be solved in time $f(|\varphi|, t) \cdot 2^{O(\Delta \cdot t)} \cdot |G|^{O(t)}$ (Theorem 6.2). Finally, in Section 7, we apply Theorem 6.2 to obtain explicit algorithms for several supergraph problems involving contraction-closed parameters.

2. Preliminaries

For each $n \in \mathbb{N}$, we let $[n] = \{1, ..., n\}$. We let $[0] = \emptyset$. For each finite set $U$, we let $\mathcal{P}(U)$ denote the set of subsets of $U$. For each $r \in \mathbb{N}$ and each finite set $U$, we let $\mathcal{P}^\leq(U, r) = \{U' \subseteq U \mid |U'| \leq r\}$ be the set of subsets of $U$ of size at most $r$, and $\mathcal{P}^= (U, r) = \{U' \subseteq U \mid |U'| = r\}$ be the set of subsets of $X$ of size precisely $r$. If $A, A_1, ..., A_k$ are sets, then we write $A = A_1 \cup A_2 \cup \ldots \cup A_k$ to indicate that $A_i \cap A_j = \emptyset$ for $i \neq j$, and that $A$ is the disjoint union of $A_1, ..., A_k$. 

Graphs: A graph is a triple \( G = (V_G, E_G, \text{Inc}_G) \) where \( V_G \) is a set of vertices, \( E_G \) is a set of edges, and \( \text{Inc}_G \subseteq E_G \times V_G \) is an incidence relation. For each \( e \in E_G \) we let \( \text{endpts}(e) = \{ v \mid \text{Inc}_G(e, v) \} \) be the set of endpoints of \( e \), and we assume that \( |\text{endpts}(e)| \) is either 0 or 2. We note that our graphs are allowed to have multiple edges, but no loops. We say that a graph \( H \) is a subgraph of \( G \) if \( V_H \subseteq V_G \), \( E_H \subseteq E_G \) and \( \text{Inc}_H = \text{Inc}_G \cap E_H \times V_H \). Alternatively, we say that \( G \) is a supergraph of \( H \). The degree of a vertex \( v \in V_G \) is the number \( d(v) \) of edges incident with \( v \). We let \( \Delta(G) \) denote the maximum degree of a vertex of \( G \).

A path in a graph \( G \) is a sequence \( v_1 e_1 v_2 ... e_{n-1} v_n \) where \( v_i \in V_G \) for \( i \in [n] \), \( e_i \in E_G \) for \( i \in [n-1] \), \( v_i \neq v_j \) for \( i \neq j \), and \( \{v_i, v_{i+1}\} = \text{endpts}(e_i) \) for each \( i \in [n-1] \). We say that \( G \) is connected if for every two vertices \( v, v' \in V_G \) there is a path whose first vertex is \( v \) and whose last vertex is \( v' \).

Let \( G \) and \( H \) be graphs. An isomorphism from \( G \) to \( H \) is a pair of bijections \( \mu = (\mu : V_G \rightarrow V_H, \overline{\mu} : E_G \rightarrow E_H) \) such that for every \( e \in E_G \) if \( \text{endpts}(e) = \{v, v'\} \) then \( \text{endpts}(\overline{\mu}(e)) = \{\overline{\mu}(v), \mu(v')\} \). We say that \( G \) and \( H \) are isomorphic if there is an isomorphism from \( G \) to \( H \).

Treewidth: A tree is an acyclic graph \( T \) containing a unique connected component. To avoid confusion we may call the vertices of a tree “nodes” and call their edges “arcs”. We let \( \text{nodes}(T) \) denote the set of nodes of \( T \) and \( \text{arcs}(T) \) denote its set of arcs. A tree decomposition of a graph \( G \) is a pair \((T, \beta)\) where \( T \) is a tree and \( \beta : \text{nodes}(T) \rightarrow \mathcal{P}(V_G) \) is a function that labels nodes of \( T \) with subsets of vertices of \( G \) in such a way that the following conditions are satisfied.

\[
\begin{align*}
(1) & \quad \bigcup_{u \in \text{nodes}(T)} \beta(u) = V_G \\
(2) & \quad \text{For every } e \in E_G, \text{ there exists a node } u \in \text{nodes}(T) \text{ such that } \text{endpts}(e) \subseteq \beta(u) \\
(3) & \quad \text{For every } v \in V_G, \text{ the set } T_v = \{ u \in \text{nodes}(T) \mid v \in \beta(u) \}, \text{ i.e., the set of nodes of } T \text{ whose corresponding bags contain } v, \text{ induces a connected subtree of } T.
\end{align*}
\]

The width of a tree decomposition \((T, \beta)\) is defined as \( \max_{u \in \text{nodes}(T)} |\beta(u)| - 1 \), that is, the maximum bag size minus one. The treewidth of a graph \( G \), denoted by \( \text{tw}(G) \), is the minimum width of a tree decomposition of \( G \).

CMSO Logic: The counting monadic second-order logic of graphs, here denoted by CMSO, extends first order logic by allowing quantifications over sets of vertices and edges, and by introducing the notion of modular counting predicates. More precisely, the syntax of CMSO logic includes the logical connectives \( \top, \land, \lor, \neg, \leftrightarrow, \Rightarrow \), variables for vertices, edges, sets of vertices and sets of edges, the quantifiers \( \exists, \forall \) that can be applied to these variables, and the following atomic predicates:

\[
\begin{align*}
(1) & \quad x \in X \text{ where } x \text{ is a vertex variable and } X \text{ a vertex-set variable}; \\
(2) & \quad y \in Y \text{ where } y \text{ is an edge variable and } Y \text{ an edge-set variable}; \\
(3) & \quad \text{Inc}(x, y) \text{ where } x \text{ is a vertex variable, } y \text{ is an edge variable, and the interpretation is that the edge } x \text{ is incident with the edge } y. \\
(4) & \quad \text{card}_{a,r}(Z) \text{ where } 0 \leq a < r, \ r \geq 2, \ Z \text{ is a vertex-set or edge-set variable, and the interpretation is that } |Z| = a \pmod{r}; \\
(5) & \quad \text{equality of variables representing vertices, edges, sets of vertices and sets of edges.}
\end{align*}
\]

A CMSO sentence is a CMSO formula without free variables. If \( \varphi \) is a CMSO sentence, then we write \( G \models \varphi \) to indicate that \( G \) satisfies \( \varphi \).
Terms: Let $\Sigma$ be a finite set. The set $\text{Ter}(\Sigma)$ of terms over $\Sigma$ is inductively defined as follows.

1. If $a \in \Sigma$, then $a \in \text{Ter}(\Sigma)$.
2. If $a \in \Sigma$, and $t \in \text{Ter}(\Sigma)$, then $a(t) \in \text{Ter}(\Sigma)$.
3. If $a \in \Sigma$, and $t_1, t_2 \in \text{Ter}(\Sigma)$, then $a(t_1, t_2) \in \text{Ter}(\Sigma)$.

Note that the alphabet $\Sigma$ is unranked and the symbols in $\Sigma$ may be regarded as function symbols or arity 0, 1 or 2. The set of positions of a term $t = a(t_1, ..., t_r) \in \text{Ter}(\Sigma)$ is defined as follows.

$$\text{Pos}(t) = \{\lambda\} \cup \bigcup_{j \in \{1, ..., r\}} \{jp \mid p \in \text{Pos}(t_j)\}.$$  

Note that $\text{Pos}(t)$ is a set of strings over the alphabet $\{1, 2\}$ and that $\lambda$ is the empty string. If $t = a$ for some $a \in \Sigma$, then $\text{Pos}(t) = \{\lambda\}$. If $p, pj \in \text{Pos}(t)$ where $j \in \{1, 2\}$, then we say that $pj$ is a child of $p$. Alternatively, we say that $p$ is the parent of $pj$. We say that $p$ is a leaf if it has no children. We let $\tau(t)$ be the tree that has $\text{Pos}(t)$ as nodes and $\{(p, pj) \mid j \in \{1, 2\}, p, pj \in \text{Pos}(t)\}$ as arcs. We say that a subset $P \subseteq \text{Pos}(t)$ is connected if the sub-tree of $\tau(t)$ induced by $P$ is connected. If $P$ is connected, then we say that a position $p \in P$ is the root of $P$ if the parent of $p$ does not belong to $P$.

If $t = a(t_1, ..., t_r)$ is a term in $\text{Ter}(\Sigma)$ for $r \in \{0, 1, 2\}$, and $p \in \text{Pos}(t)$, then the symbol $t[p]$ at position $p$ is inductively defined as follows. If $p = \lambda$, then $t[p] = a$. On the other hand, if $p = jp'$ where $j \in \{1, 2\}$, then $t[p] = t_j[p']$.

Tree Automata: Let $\Sigma$ be a finite set of symbols. A bottom-up tree-automaton over $\Sigma$ is a tuple $\mathcal{A} = (Q, \Sigma, F, \Delta)$ where $Q$ is a set of states, $F \subseteq Q$ a set of final states, and $\Delta$ is a set of transitions of the form $(q_1, ..., q_r, a, q)$ with $a \in \Sigma$, $0 \leq r \leq 2$, and $q_1, ..., q_r, q \in Q$. The size of $\mathcal{A}$, which is defined as $|\mathcal{A}| = |Q| + |\Delta|$, measures the number of states in $Q$ plus the number of transitions in $\Delta$. The set $\mathcal{L}(\mathcal{A}, q, i)$ of all terms reaching a state $q \in Q$ in depth at most $i$ is inductively defined as follows.

$$\mathcal{L}(\mathcal{A}, q, 1) = \{a \mid (a, q) \in \Delta\}$$

$$\mathcal{L}(\mathcal{A}, q, i) = \mathcal{L}(\mathcal{A}, q, i - 1) \cup \{a(t_1, ..., t_r) \mid r \in \{1, 2\}, \exists(q_1, ..., q_r, a, q) \in \Delta, t_j \in \mathcal{L}(\mathcal{A}, q_j, i - 1)\}$$

We denote by $\mathcal{L}(\mathcal{A}, q)$ the set of all terms reaching state $q$ in finite depth, and by $\mathcal{L}(\mathcal{A})$ the set of all terms reaching some final state in $F$.

$$\mathcal{L}(\mathcal{A}, q) = \bigcup_{i \in \mathbb{N}} \mathcal{L}(\mathcal{A}, q, i) \quad \mathcal{L}(\mathcal{A}) = \bigcup_{q \in F} \mathcal{L}(\mathcal{A}, q) \quad (2.1)$$

We say that the set $\mathcal{L}(\mathcal{A})$ is the language accepted by $\mathcal{A}$.

Let $\pi : \Sigma \rightarrow \Sigma'$ be a map between finite sets of symbols $\Sigma$ and $\Sigma'$. Such mapping can be homomorphically extended to a mapping $\pi : \text{Ter}(\Sigma) \rightarrow \text{Ter}(\Sigma')$ between terms by setting $\pi(t)[p] = \pi(t[p])$ for each position $p \in \text{Pos}(t)$. Additionally, $\pi$ can be further extended to a set of terms $\mathcal{L} \subseteq \text{Ter}(\Sigma)$ by setting $\pi(\mathcal{L}) = \{\pi(t) \mid t \in \text{Ter}(\Sigma)\}$. Below we state some well known closure and decidability properties for tree automata.

**Lemma 2.1** (Properties of Tree Automata [CDG+07]). Let $\Sigma$ and $\Sigma'$ be finite sets of symbols. Let $\mathcal{A}_1$ and $\mathcal{A}_2$ be tree automata over $\Sigma$, and $\pi : \Sigma \rightarrow \Sigma'$ be a mapping.
One can construct in time $O(|A_1| \cdot |A_2|)$ a tree automaton $A_1 \cap A_2$ such that $\mathcal{L}(A_1 \cap A_2) = \mathcal{L}(A_1) \cap \mathcal{L}(A_2)$.

(2) One can determine whether $\mathcal{L}(A_1) \neq \emptyset$ in time $O(|A_1|)$.

(3) One can construct in time $O(|A_1|)$ a tree automaton $\pi(A_1)$ such that $\mathcal{L}(\pi(A_1)) = \pi(\mathcal{L}(A_1))$.

3. Concrete Tree Decompositions

A $t$-concrete bag is a pair $(B, b)$ where $B \subseteq [t]$, and $b \subseteq B$ with $b = \emptyset$ or $|b| = 2$. We note that $B$ is allowed to be empty. We let $\mathcal{B}(t)$ be the set of all $t$-concrete bags. Note that $|\mathcal{B}(t)| \leq t^2 \cdot 2^t$. We regard the set $\mathcal{B}(t)$ as a finite alphabet which will be used to construct terms representing tree decompositions of graphs.

A $t$-concrete tree decomposition is a term $T \in \text{Ter}(\mathcal{B}(t))$. We let $T[p] = (T[p], B, T[p], b)$ be the $t$-concrete bag at position $p$ of $T$. For each $s \in [t]$, we say that a non-empty subset $P \subseteq \text{Pos}(T)$ is $s$-maximal if the following conditions are satisfied.

(1) $P$ is connected in $\text{Pos}(T)$.

(2) $s \in T[p], B$ for every $p \in P$.

(3) If $P'$ is a connected subset of $\text{Pos}(T)$ and $s \in T[p], B$ for every $p \in P'$, then either $P \cap P' = \emptyset$ or $P' \subseteq P$.

Note that if $P$ and $P'$ are $s$-maximal then either $P = P'$, or $P \cap P' = \emptyset$. Additionally, for each $p \in \text{Pos}(T)$, and each $s \in T[p], B$, there exists a unique subset $P \subseteq \text{Pos}(T)$ such that $P$ is $s$-maximal and $p \in P$. We denote this unique set by $P(p, s)$. Intuitively, each such set $P(p, s)$ corresponds to a vertex in the graph represented by $T$. Two disjoint $s$-maximal sets $P(p, s)$ and $P(p', s)$ correspond to two distinct vertices in the graph.

**Definition 3.1.** Let $T \in \text{Ter}(\mathcal{B}(t))$. The graph $\mathcal{G}(T)$ associated with $T$ is defined as follows.

(1) $V_{\mathcal{G}(T)} = \{v_{s,p} \mid s \in [t], P \subseteq \text{Pos}(T), P$ is $s$-maximal\}.

(2) $E_{\mathcal{G}(T)} = \{e_p \mid p \in \text{Pos}(T), b \neq \emptyset\}$.

(3) $\text{Inc}_{\mathcal{G}(T)} = \{(e_p, v_{s,p}(p, s)) \mid e_p \in E_{\mathcal{G}(T)}, s \in T[p], b\}$.

Intuitively, a $t$-concrete tree decomposition may be regarded as a way of representing a graph together with one of its tree decompositions. This idea is widespread in texts dealing with recognizable properties of graphs [BP16, AGK08, CE12, Elb16, FFG02]. Within this framework it is customary to define a bag of width $t$ as a graph with at most $t$ vertices together with a function that labels the vertices of these graphs with numbers from $\{1, \ldots, t\}$. Our notion of $t$-concrete bag, on the other hand, may be regarded as a representation of a graph with at most $t$ vertices injectively labeled with numbers from $\{1, \ldots, t\}$ and at most one edge. Within this point of view, the representation used here is a syntactic restriction of the former. On the other hand, any decomposition which uses bags with arbitrary graphs of size $t$ can be converted into a $t$-concrete decomposition, by expanding each bag into a sequence of $t^2$ concrete bags. The following observation is immediate, using the fact that if a graph has treewidth $t$, then it has a rooted tree decomposition in which each node has at most two children [Elb16].

**Observation 3.2.** A graph $G$ has treewidth $t$ if and only if there exists some $(t+1)$-concrete tree decomposition $T \in \text{Ter}(\mathcal{B}(t+1))$ such that $\mathcal{G}(T)$ is isomorphic to $G$. 
Theorem 3.3 (Variant of Courcelle’s Theorem). There exists a computable function \( f : \mathbb{N} \times \mathbb{N} \to \mathbb{N} \) such that for each CMSO sentence \( \varphi \), and each \( t \in \mathbb{N} \), one can construct in time \( f(|\varphi|, t) \) a tree-automaton \( \mathcal{A}(\varphi, t) \) accepting the following tree language.

\[
\mathcal{L}(\mathcal{A}(\varphi, t)) = \{ T \in \text{Ter}(\mathcal{B}(t)) \mid \mathcal{G}(T) \models \varphi \}.
\]

(3.1)

4. Sub-Decompositions

In this section we introduce the notion of sub-decompositions of a \( t \)-concrete decomposition. Intuitively, if a \( t \)-concrete tree decomposition \( T \) represents a graph \( G \) then sub-decompositions of \( T \) represent subgraphs of \( G \). The main result of this section states that given a tree automaton \( \mathcal{A} \) over \( \mathcal{B}(t) \), one can efficiently construct a tree automaton \( \text{Sub}(\mathcal{A}) \) over \( \mathcal{B}(t) \) which accepts precisely the sub-decompositions of \( t \)-concrete tree decompositions in \( \mathcal{L}(\mathcal{A}) \).

We say that a \( t \)-concrete bag \((B, b)\) is a sub-bag of a \( t \)-concrete bag \((B', b')\) if \( B \subseteq B' \) and \( b \subseteq b' \).

Definition 4.1. We say that a \( t \)-concrete tree decomposition \( T \in \text{Ter}(\mathcal{B}(t)) \) is a sub-decomposition of a \( t \)-concrete tree decomposition \( T' \in \text{Ter}(\mathcal{B}(t)) \) if the following conditions are satisfied.

**S1.** \( \text{Pos}(T) = \text{Pos}(T') \).

**S2.** For each \( p \in \text{Pos}(T) \), \( T[p] \) is a sub-bag of \( T'[p] \).

**S3.** For each \( p, pj \in \text{Pos}(T) \), and for each \( s \in [t] \), if \( s \in T'[p].B \) and \( s \in T'[pj].B \), then \( s \notin T[p].B \) if and only if \( s \notin T[pj].B \).

The following theorem states that sub-decompositions of \( T' \) are in one to one correspondence with subgraphs of \( \mathcal{G}(T') \).

Theorem 4.2. Let \( G \) and \( G' \) be graphs and let \( T' \in \text{Ter}(\mathcal{B}(t)) \) be a \( t \)-concrete tree decomposition such that \( \mathcal{G}(T') = G' \). Then \( G \) is a subgraph of \( G' \) if and only if there exists some \( T \in \text{Ter}(\mathcal{B}(t)) \) such that \( T \) is a sub-decomposition of \( T' \) with \( \mathcal{G}(T) = G \).

Proof.

(1) Let \( G \) be a subgraph of \( \mathcal{G}(T') \). We show that there exists a sub-decomposition \( T \) of \( T' \) such that \( \mathcal{G}(T) = G \). Since \( G \) is a subgraph of \( \mathcal{G}(T) \), we have that \( V_G \subseteq V_{\mathcal{G}(T')} \), \( E_G \subseteq E_{\mathcal{G}(T')} \), and \( \text{Inc}_G = \text{Inc}_{\mathcal{G}(T')} \cap E_G \times V_G \). We define \( T \) by setting \( T[p] = \text{Pos}(T') \) as follows for each \( p \in \text{Pos}(T) \).

(a) \( T[p].B = T'[p].B \setminus \{ s \mid v_{s,p}(p, s) \in V_{\mathcal{G}(T')} \setminus V_G \} \).

(b) \( T[p].b = 0 \) if \( e_p \in E_{\mathcal{G}(T')} \setminus E_G \) and \( T[p].b = T'[p].b \) otherwise.

First, we note that \( v_{s,p} \in V_{\mathcal{G}(T)} \) if and only if \( v_{s,p} \in V_{\mathcal{G}(T)} \text{ and } e_p \in E_{\mathcal{G}(T)} \) if and only if \( e_p \in E_G \) and \( (e_p, v_{i,p}) \in \text{Inc}_{\mathcal{G}(T)} \) if and only if \( (e_p, v_{i,p}) \in V_G \). Therefore, \( G = \mathcal{G}(T) \). We will check that the \( t \)-concrete decomposition \( T \) defined above is indeed a sub-decomposition of \( T' \). In other words, we will verify that conditions S1, S2 and S3 above are satisfied. The fact that S1 is satisfied is immediate, since we define \( T[p] \) for each \( p \in \text{Pos}(T') \). Therefore, \( \text{Pos}(T) = \text{Pos}(T') \). Condition S2 is also satisfied, since by (a) and (b) we have that \( T[p].B \subseteq T'[p].B \) and that \( T[p].b \) is either 0, or equal to \( T'[p].b \). Finally, condition S3 is also satisfied, since (a) guarantees that for each number \( s \in [t] \), and...
each s-maximal set \( P \subseteq Pos(T') \), if \( s \) is removed from \( T'[p]_B \) for some \( p \in P \), then \( s \) is indeed removed from \( T'[p]_B \) for every \( p \in P \).

(2) For the converse, let \( T \) be a sub-decomposition of \( T' \). We show that the graph \( G(T) \) is a subgraph of \( G(T') \). First, we note that condition \( S3 \) guarantees that for each \( s \in [t] \) and each \( P \subseteq Pos(T) \), if \( P \) is s-maximal in \( T \) then \( P \) is s-maximal in \( T' \). Therefore, \( V_G(T) \subseteq V_G(T') \). Now, Condition \( S2 \) guarantees that \( e_p \in E_G(T) \) implies that \( e_p \in E_G(T') \). Therefore, \( E_{G(T)} \subseteq E_{G(T')} \). Finally, by definition \( (e_p, v_{s,p}) \in Inc_{G(T)} \) if and only if \( s \in T[p], b \) for each \( p \in P \). Since the fact that \( s \in T[p], b \) implies that \( s \in T'[p], b \), we have that \( (e_p, v_{s,p}) \in Inc_{G(T')} \) implies that \( (e_p, v_{s,p}) \in Inc_{G(T')} \). Therefore, \( Inc_{G(T)} \subseteq Inc_{G(T')} \). Additionally, since \( (e_p, v_{s,p}(s,p)) \in Inc_{G(T)} \) for each \( e_p \in E_G(T) \) and each \( s \in T[p], b \), we have that \( Inc_{G(T)} = Inc_{G(T')} \cap E_G(T) \times V_G(T) \). This shows that \( G(T) \) is a subgraph of \( G(T') \).

The following theorem states that given a tree automaton \( A \) over \( B(t) \), one can efficiently construct a tree automaton \( Sub(A) \) which accepts precisely the sub-decompositions of \( t \)-concrete tree decompositions in \( L(A) \).

**Theorem 4.3 (Sub-Decomposition Automaton).** Let \( A \) be a tree automaton over \( B(t) \). Then one can construct in time \( 2^{O(t)} \cdot |A| \) a tree automaton \( Sub(A) \) over \( B(t) \) accepting the following language.

\[
L(Sub(A)) = \{ T \in Ter(B(t)) \mid \exists T' \in L(A) \text{ s.t. } T \text{ is a sub-decomposition of } T' \}.
\]

**Proof.** Let \( A = (Q, B(t), \Delta, F) \) be a tree automaton over \( B(t) \). As a first step we create an intermediate tree automaton \( A' = (Q', B(t), \Delta', F') \) which accepts the same language as \( A \). The tree automaton \( A' \) is defined as follows.

\[
Q' = \{ q_B \mid q \in Q, B \subseteq [t] \} \quad F' = \{ q_B \mid q \in F, B \subseteq [t] \}
\]

\[
\Delta' = \{ (q_{B_1}, ..., q_{B_r}, (B, b), q_B) \mid (q^1, ..., q^r, (B, b), q) \in \Delta, B_i \subseteq [t] \text{ for } i \in [r] \}.
\]

Note that for each \( q \in Q, \) each \( B \subseteq [t], \) and each \( T \in Ter(B(t)), \) \( T \) reaches state \( q_B \) in \( A' \) if and only if \( \text{T reaches state } q \text{ in } A \) and \( T[\lambda], B = B \), where \( T[\lambda] \) is the \( t \)-concrete bag at the root of \( T \). In particular, this implies that a term \( T \) belongs to \( L(A') \) if and only if \( T \in L(A) \).

Now, consider the tree automaton \( Sub(A) = (Q'', B(t), \Delta'', F'') \) over \( B(t) \) where

\[
Q'' = \{ q_{B, B'} \mid q \in Q, B \subseteq B' \subseteq [t] \} \quad F'' = \{ q_{B, B'} \mid q \in F, B \subseteq B' \subseteq [t] \}
\]

\[
\Delta'' = \{ (q_{B_1, B_1'}, ..., q_{B_r, B_r'}, (B, b), q_{B, B'}) \mid \exists (q^1_{B_1'}, ..., q^r_{B_r'}, (B', b'), q_{B', B'}) \in \Delta' \text{ such that } B_i \subseteq B_i', B \subseteq B', (B, b) \text{ is a sub-bag of } (B', b') \text{ for each } j \in [r], \text{ if } s \in B' \wedge s \in B_j \text{ then } s \notin B \iff s \notin B_j \}.
\]

It follows by induction on the height of terms that a term \( T \in Ter(B(t)) \) reaches a state \( q_{B, B'} \) in \( Sub(A) \) if and only if there exists some term \( T' \in Ter(B(t)) \) such that \( T' \) reaches state \( q_{B', B''} \) in \( A' \), \( T'[\lambda], B = B, T''[\lambda], B = B' \), and \( T \) is a sub-decomposition of \( T' \). In particular, \( T \) reaches a final state of \( Sub(A) \) if and only if \( T \) is a sub-decomposition of some \( T' \) which reaches a final state of \( A' \).
5. Representing All Tree Decompositions of a Given Graph

In this section we show that given a connected graph \( G \) of maximum degree \( \Delta \), and a positive integer \( t \), one can construct in time \( 2^{O(\Delta t)} \cdot |V_G|^{O(t)} \) a tree automaton \( \mathcal{A}(G, t) \) over \( \mathcal{B}(t) \) that accepts the set of all \( t \)-concrete tree decompositions of \( G \) (of all shapes and sizes).

Let \( G \) be a graph. A \((G, t)\)-concrete bag is a tuple \((B, b, \nu, \eta, y, \rho)\) where \((B, b)\) is a \( t \)-concrete bag; \( \nu : B \rightarrow V_G \) is an injective function that assigns a vertex of \( G \) to each element of \( B \); \( \eta : B \rightarrow \mathcal{P}^{\leq}(E_G, \Delta(G)) \) is a function that assigns to each element \( s \in B \) a set of edges incident with \( \nu(s) \) of size at most \( \Delta(G) \); \( y \) is a subset of \( E_G \) such that \( |y| \leq 1 \) and \( y \subseteq \eta(s) \) whenever \( s \in B \); and \( \rho \) is a subset of \( B \).

We let \( \mathcal{B}(G, t) \) be the set of all \((G, t)\)-concrete bags. Note that \( \mathcal{B}(G, t) \) has at most \( 2^{O(\Delta(G) \cdot t)} \cdot |V_G|^{O(t)} \) elements. We let \( \text{Ter}(\mathcal{B}(G, t)) \) be the set of all terms over \( \mathcal{B}(G, t) \). If \( T \) is a term in \( \mathcal{B}(G, t) \) then for each \( p \in \text{Pos}(T) \), the \((G, t)\)-concrete bag of \( T \) at position \( p \) is denoted by the tuple

\[
(\hat{T}[p].B, \hat{T}[p], b, \hat{T}[p].\nu, \hat{T}[p].\eta, \hat{T}[p].y, \hat{T}[p].\rho).
\]

**Definition 5.1.** We say that a term \( \hat{T} \in \text{Ter}(\mathcal{B}(G, t)) \) is a \((G, t)\)-concrete tree decomposition if the following conditions are satisfied for each \( p \in \text{Pos}(\hat{T}) \) and each \( s \in [t] \).

**C1.** If \( p[j] \in \text{Pos}(\hat{T}) \) and \( s \in \hat{T}[p].B \cap \hat{T}[p[j]].B \) then \( \hat{T}[p].\nu(s) = \hat{T}[p[j]].\nu(s) \).

**C2.** If \( \hat{T}[p].b = \{s, s'\} \) then \( \hat{T}[p].y = \{e\} \) for some edge \( e \) with \( \text{endpts}(e) = \{\hat{T}[p].\nu(s), \hat{T}[p].\nu(s')\} \).

**C3.** Let \( r \in \{0, 1, 2\} \), and \( p_1, \ldots, p_r \) be the children\(^3\) of \( p \), then

\[
\hat{T}[p].\eta(s) = \hat{T}[p].y \cup \hat{T}[p[1]].\eta(s) \cup \ldots \cup \hat{T}[p[r]].\eta(s).
\]

**C4.** If \( s \in \hat{T}[p].\rho \) then \( \hat{T}[p].\eta(s) = \{e | (e, \hat{T}[p].\nu(s)) \in \text{Endpt}_G\} \).

**C5.** If \( p = \lambda \) then \( \hat{T}[p], \rho = \hat{T}[p].B \). If \( p[j] \in \text{Pos}(\hat{T}) \) then \( s \in \hat{T}[p[j]].\rho \) if and only if \( s \in \hat{T}[p[j]].B \) and \( s \notin \hat{T}[p].B \).

Let \( \pi : \mathcal{B}(G, t) \rightarrow \mathcal{B}(t) \) be a function such that \( \pi((B, b, \nu, \eta, y, \rho)) = (B, b) \) for each \((G, t)\)-concrete bag \((B, b, \nu, \eta, y, \rho) \in \mathcal{B}(G, t) \). In other words, \( \pi \) transforms a \((G, t)\)-concrete bag into a \( t \)-concrete bag by erasing the four last coordinates of the former. If \( T \) is a term in \( \text{Ter}(\mathcal{B}(G, t)) \) then we let \( \pi(T) \) be the term in \( \text{Ter}(\mathcal{B}(t)) \) which is obtained by setting \( \pi(\hat{T})[p] = \pi(\hat{T}[p]) \) for each position \( p \in \text{Pos}(\hat{T}) \).

**Theorem 5.2.** Let \( G \) be a connected graph and let \( T \in \text{Ter}(\mathcal{B}(t)) \). Then \( T \) is a \( t \)-concrete tree decomposition of \( G \) if and only if \( |V_G(T)| = |V_G| \) and there exists a \((G, t)\)-concrete tree decomposition \( \hat{T} \in \text{Ter}(\mathcal{B}(G, t)) \) such that \( \pi(\hat{T}) = T \).

**Proof.** Assume that \( G = \mathcal{G}(T) \). Then we have \( |V_G| = |V_G(T)| \). We will show how to construct a \((G, t)\)-concrete tree decomposition \( \hat{T} \in \text{Ter}(\mathcal{B}(G, t)) \) such that \( \pi(\hat{T}) = T \). Clearly, we must have \( \text{Pos}(\hat{T}) = \text{Pos}(T) \), and for each \( p \in \text{Pos}(T) \), we must have \( \hat{T}[p].B = T[p].B \) and \( \hat{T}[p].b = T[p].b \). Additionally, the set \( \hat{T}[p].\rho \) is completely determined by the sets \( T[p].B \) and \( T[p'].B \), where \( p' \) is the parent of \( p \). Therefore, it is enough to specify the functions \( \hat{T}[p].\nu, \hat{T}[p].\eta, \) and the set \( \hat{T}[p].y \) for each \( p \in \text{Pos}(T) \).

---

\(^3\)If \( r = 0 \) then \( p \) has no child.
Let $\beta : \text{Pos}(T) \rightarrow \{\emptyset, \{e_p\}\}$ be a function such that for each $p \in \text{Pos}(T)$, $\beta(p) = \emptyset$ if $T[p].b = 0$ and $\beta(p) = \{e_p\}$ if $T[p].b \neq 0$.

1. For each $p \in \text{Pos}(T)$ and each $s \in \hat{T}[p].B$ we set $\hat{T}[p].\nu(s) = v_{s,p(s,p)}$.
2. For each $p \in \text{Pos}(T)$ such that $T[p].b \neq 0$, we set $\hat{T}[p].y = \{e_p\}$.
3. For each $p \in \text{Pos}(T)$, and each $s \in \hat{T}[p].B$, we set
   \[
   \hat{T}[p].\eta(s) = \begin{cases}
   \beta(p) \cup \hat{T}[p1].\eta(s) \cup \ldots \cup \hat{T}[pr].\eta(s) & \text{if } s \in \hat{T}[p].b, \\
   \hat{T}[p1].\eta(s) \cup \ldots \cup \hat{T}[pr].\eta(s) & \text{otherwise},
   \end{cases}
   \]

   where $p1, \ldots, pr$ are the children of $p$.

   Now one can check by induction on the height of positions that for each $s \in [t]$ and each position $p \in \text{Pos}(\hat{T})$, the five conditions C1-C5 of Definition 5.1 are satisfied. This implies that $\hat{T}$ is a $(G,t)$-concrete tree decomposition.

For the converse, suppose that $T \in \text{Ter}(\mathcal{E}(G,t))$ is a $(G,t)$-concrete tree decomposition such that $T = \pi(T)$ and $|V_{\hat{G}(T)}| = |V_G|$. We will show that $G(T)$ is isomorphic to $G$. Let $\hat{\mu} : V_{\hat{G}(T)} \rightarrow V_G$ and $\hat{\mu} : E_{\hat{G}(T)} \rightarrow E_G$ be functions that are defined as follows for each vertex $v_{s,p} \in V_{\hat{G}(T)}$ and each edge $e_p \in E_{\hat{G}(T)}$ respectively.

\[
\hat{\mu}(v_{s,p}) = \hat{T}[p].\nu(s) \text{ if } P = P(s,p) \text{ for some } p \in P.
\]

(5.1)

\[
\hat{\mu}(e_p) = e \text{ if } \hat{T}[p].y = \{e\}.
\]

(5.2)

We claim that the pair $\mu = (\hat{\mu}, \hat{\mu})$ is an isomorphism from $G(T)$ to $G$. First, let $(e_p, v_{s,p}) \in \text{Inc}_{\hat{G}(T)}$. Then, by Equation 3 of Definition 3.1, we have that $s \in \hat{T}[p].b$. Therefore, by Equation 5.2 and by Condition C2 of Definition 5.1, $(\hat{T}[p].b, \hat{T}[p].\nu(s)) \in \text{Inc}_G$.

Since by Equation 5.1, $\hat{\mu}(v_{s,p}) = \hat{T}[p].\nu(s)$, we have that $(\hat{T}[p].b, \hat{\mu}(v_{s,p})) \in \text{Inc}_G$. In other words, whenever $(e_p, v_{s,p}) \in \text{Inc}_{\hat{G}(T)}$, we have that $(\hat{T}[p].b, \hat{\mu}(v_{s,p})) \in \text{Inc}_G$. This shows that the pair $\mu$ is a morphism from $G(T)$ to $G$ in the sense that it preserves adjacencies. In order to show that $\mu$ is indeed an isomorphism, we need to prove that the functions $\hat{\mu}$ and $\hat{\mu}$ are bijections.

Since by assumption we have that $|V_G| = |V_{\hat{G}(T)}|$, to show that $\hat{\mu}$ is a bijection, it is enough to show that for each vertex $v \in V_G$ there is some vertex $v_{s,p} \in V_{\hat{G}(T)}$ such that $\hat{\mu}(v_{s,p}) = v$. In other words, it is enough to show that $\hat{\mu}$ is surjective. This proceeds as follows. Let $v \in V_G$ and $v_{s,p} \in V_{\hat{G}(T)}$ be such that $\hat{\mu}(v_{s,p}) = v$. By Equation 5.1, there is some $p \in P$ such that $\hat{T}[p].\nu(s) = v$. Therefore, since $P = P(s,p)$, by Condition C1 of Definition 5.1, $\hat{T}[p].\nu(s) = v$ for every $p \in P$. By Conditions C3 and C4 of Definition 5.1, for each edge $e$ such that $(e, v) \in \text{Inc}_G$, there exists a (unique) $p \in P$ such that $\hat{T}[p].y = \{e\}$. Now, let $p \in P$, and $e$ be the unique edge such that $\hat{T}[p].y = \{e\}$ and assume that $\text{endpts}(e) = \{v, v'\}$. Then by Condition C2, there is some $s'$ such that $\hat{T}[p].b = \{s, s'\}$ and $\hat{T}[p].\nu(s') = v'$. Therefore, by Equation 5.1, we have that $\hat{\mu}(v_{s',p(s',p)}) = v'$. In other words, we have shown that if $\hat{\mu}(v_{s',p}) = v'$, then for each neighbour $v'$ of $v$, there is some $p \in P$ and some $s' \in [t]$ such that $\hat{\mu}(v_{s',p(s',p)}) = v'$. Since $G$ is connected, this implies that for each $v \in V_G$ there is some $v_{s,p}$ such that $\hat{\mu}(v_{s,p}) = v$.

Now, it remains to show that the function $\hat{\mu}$ is also a bijection. Let $e$ be an edge in $E_G$, and let $v$ be an endpoint of $e$. Then there is some $v_{s,p} \in G(T)$ such that $\hat{\mu}(v_{s,p}) = v$. By the discussion above, this implies that for some $p \in P$, $\hat{T}[p].y = \{e\}$. Therefore, by Equation 5.2,
Lemma 5.3. Let \( G \) be a tree automaton of maximum degree \( \Delta \) which accepts a term \( \hat{T} \in \text{Ter}(B(G,t)) \) if and only if \( \hat{T} \) is a \((G,t)\)-concrete tree decomposition.

\[
\mathcal{L}(\hat{A}(G,t)) = \{ \hat{T} \in \text{Ter}(B(G,t)) \mid \hat{T} \text{ is a } (G,t)\text{-concrete tree decomposition.} \} \tag{5.3}
\]

Proof. Let \( \hat{B}_1, ..., \hat{B}_r, \hat{B} \) be \((G,t)\)-concrete bags for \( 0 \leq r \leq 2 \), where \( \hat{B} = (B,b,\nu,\eta,y) \) and \( \hat{B}_j = (B_j,b_j,\nu_j,\eta_j,y_j) \) for \( j \in [r] \). We say that the tuple \( (\hat{B}_1, ..., \hat{B}_r, \hat{B}) \) is \((G,t)\)-compatible if the following conditions are satisfied for each \( s \in [t] \).

1. If \( s \in B_j \cap B \) for some \( j \in [r] \) then \( \nu(s) = \nu_j(s) \).
2. If \( s \in b \) then \( y = \{ e \} \) for some edge \( e \) such that \( (e,\nu(e)) \in \text{Inc}_G \).
3. \( \eta(s) = y \cup \eta_1(s) \cup ... \cup \eta_r(s) \).
4. If \( s \in \rho \) then \( \eta(s) = \{ e \mid (e,\nu(e)) \in \text{Inc}_G \} \).
5. \( s \in \rho_j \) if and only if \( s \in B_j \) and \( s \notin B \).

We define the tree automaton \( \hat{A} = (Q,B(G,t),F,\Delta) \) as follows.

\[
Q = \{ q_B \mid \hat{B} \text{ is a } (G,t)\text{-concrete bag.} \} \quad F = \{ q_B \in Q \mid \hat{B}\cdot\rho = \hat{B}\cdot B \} \tag{5.4}
\]

\[ \Delta = \{ (q_{\hat{B}_1}, ..., q_{\hat{B}_r}, \hat{B}, q_{\hat{B}}) \mid (\hat{B}_1, ..., \hat{B}_r, \hat{B}) \text{ is } (G,t)\text{-compatible.} \} \]

Now, it can be shown by induction on the height of terms that a term \( \hat{T} \in \text{Ter}(B(G,t)) \) reaches a state \( q_B \) if and only if \( \hat{T}[\lambda] = \hat{B} \) and that conditions C1-C5 of Definition 5.1 are satisfied for each \( p \in \text{Pos}(T) \) and each \( s \in [t] \). In particular, this implies that \( \hat{A}(G,t) \) accepts a term \( \hat{T} \in \text{Ter}(B(G,t)) \) if and only if \( \hat{T} \) is a \((G,t)\)-concrete tree decomposition.

The next lemma states that for each positive integers \( t \) and \( n \), one can efficiently construct a tree automaton \( \hat{A}(t,n) \) which accepts precisely those \( t\)-concrete tree decompositions which give rise to graphs with \( n \) vertices.

Lemma 5.4. Let \( t \) and \( n \) be positive integers with \( t \leq n \). One can construct in time \( 2^{O(t)} \cdot n^3 \) a tree automaton \( \hat{A}(t,n) \) over \( B(t) \) accepting the following language.

\[
\mathcal{L}(\hat{A}(t,n)) = \{ T \in \text{Ter}(B(t)) \mid |V_G(T)| = n \}
\]
Proof. Let $T$ be a term in $\text{Ter}(B(t))$. Recall that for each position $p \in \text{Pos}(T)$, and each $s \in [t]$, the set $P(s,p)$ is the unique $s$-maximal subset of $\text{Pos}(T)$ that contains position $p$. We say that $(s, p)$ is a $T$-root-pair if $p$ is the root of $P(s,p)$. We note that the number of vertices of the graph $G(T)$ is equal to the number of $T$-root-pairs in $[t] \times \text{Pos}(T)$. Therefore, in order to construct an automaton that accepts precisely the terms $T \in \text{Pos}(T)$ that give rise to graphs with $n$ vertices, it is enough to define an automaton that accepts precisely those terms $T$ that admit $n$ $T$-root-pairs.

A root marking for a set $B \subseteq [t]$ is a set $\rho \subseteq B$. The automaton $A(t, n) = (Q, B(t), F, \Delta)$ is defined as follows.

$$Q = \{q_{B, \rho, j} \mid j \in \{0, \ldots, n\}, B \subseteq [t], \rho \text{ is a root marking for } B\}$$

$$F = \{q_{B, \rho, n}\}$$

$$\Delta = \{(q_{B_1, \rho_1, j_1}, \ldots, q_{B_r, \rho_r, j_r}, (B, b), q_{B, \rho, j}) \mid 0 \leq r \leq 2, (B, b) \in B(t), j = |\rho| + \sum_{i=1}^{r} |\rho_i|, \text{ for each } s \in [t], \text{ if } s \in \rho_i \text{ for some } i \in [r] \text{ then } s \notin B\}$$

Then it follows by induction on the height of terms that a term $T \in \text{Ter}(B(t))$ reaches a state $q_{B, \rho, j}$ if and only if $T[\lambda].B = B$, $(s, \lambda)$ is a $T$-root-pair for each $s \in \rho$, and $j$ is the number of $T$-root-pairs in $[t] \times \text{Pos}(T)$. In particular, the number of $T$-root-pairs is equal to $n$ if and only if $T$ reaches some final state of $A$. Note that since $|B(t)| = 2^{O(t)}$, and since $r \leq 2$, there are at most $2^{O(t)} \cdot n$ states in $Q$ and at most $2^{O(t)} \cdot n^3$ transitions in $\Delta$. Therefore, $A(t, n)$ can be constructed in time $2^{O(t)} \cdot n^3$.

The main result of this section (Theorem 5.5), follows by a combination of Theorem 5.2, Lemma 5.3 and Lemma 5.4.

**Theorem 5.5.** Let $G$ be a connected graph of treewidth $t$ and maximum degree $\Delta$. Then one can construct in time $2^{O(\Delta t)} \cdot |V_G|^{O(t)}$ a tree automaton $A(G, t)$ over $B(t)$ such that for each $T \in \text{Ter}(B(t))$, $T \in L(A(G, t))$ if and only if $T$ is a concrete tree decomposition of $G$.

Proof. By Lemma 5.3, one can construct in time $2^{O(\Delta t)} \cdot |V_G|^{O(t)}$ a tree automaton $\hat{A}(G, t)$ over $B(G, t)$ which accepts precisely the $(G, t)$ concrete tree decompositions that belong to $\text{Ter}(B(G, t))$.

Therefore, the tree automaton $\pi(A)$ accepts precisely those $t$-concrete tree decompositions $T \in \text{Ter}(B(t))$ such that $T = \pi(T)$ for some $(G, t)$-concrete tree decomposition $T \in L(\hat{A}(G, t))$. Note that $\pi(\hat{A}(G, t))$ can be constructed in time $O(|\hat{A}(G, t)|)$ by Lemma 2.1.

Now, by Lemma 5.4 we can construct in time $2^{O(t)} \cdot |V_G|^{O(t)}$ a tree automaton $A(t, |V_G|)$ over $B(t)$ which accepts a $t$-concrete tree decomposition in $\text{Ter}(B(t))$ if and only if $|V_{\hat{G}(t)}| = |V_G|$.

Therefore if we set $A(G, t) = \pi(\hat{A}(G, t)) \cap A(t, |V_G|)$, then we have that $A(G, t)$ accepts precisely those $t$-concrete tree decompositions $T \in B(t)$ such that $|V_{\hat{G}(t)}| = |V_G|$ and $T = \pi(T)$ for some $(G, t)$-concrete tree decomposition $T$. By Lemma 2.1, $A(G, t)$ can be constructed in time $2^{O(\Delta t)} \cdot |V_G|^{O(t)}$.

6. $(\varphi, t)$-Supergraphs

Let $\varphi$ be a CMSO sentence, and $t$ be a positive integer. Let $G$ and $G'$ be graphs. We say that $G'$ is a $(\varphi, t)$-supergraph of $G$ if the following three conditions are satisfied: $G' \models \varphi$, $G'$ has treewidth at most $t$, and $G$ is a subgraph of $G'$.
Lemma 6.1. Let $\varphi$ be a CMSO sentence and $t$ be a positive integer. Then a graph $G$ has a $(\varphi, t)$-supergraph if and only if there exists a $(t + 1)$-concrete tree decomposition $T \in \mathcal{L}(\text{Sub}(A(\varphi, t + 1)))$ such that $G(T)$ is isomorphic to $G$.

Proof. Assume that $G$ is a graph that has a $(\varphi, t)$-supergraph $G'$. Then $G'$ satisfies $\varphi$, $G'$ has treewidth at most $t$, and $G$ is a subgraph of $G'$. By Observation 3.2, $G'$ has a $(t + 1)$-concrete tree decomposition $T' \in \text{Ter}(B(t + 1))$, and therefore by Theorem 3.3, $T' \in \mathcal{L}(A(\varphi, t))$. Since $G$ is a subgraph of $G'$, by Theorem 4.2, $T'$ has a sub-decomposition $T$ which is a $(t + 1)$-concrete tree decomposition of $G$. Therefore, $T$ belongs to $\text{Sub}(A(\varphi, t + 1))$.

For the converse, let $T \in \mathcal{L}(\text{Sub}(A(\varphi, t + 1)))$ and let $T$ be a $(t + 1)$-concrete tree decomposition of $G$. Then $T$ is a sub-decomposition of some $(t + 1)$-concrete tree decomposition $T'$ in $\mathcal{L}(A(\varphi, t + 1))$. By Theorem 3.3, $T'$ is a $(t + 1)$-concrete tree decomposition of some graph $G'$ of treewidth at most $t$ such that $G' \models \varphi$. Since $T$ is a sub-decomposition of $T'$, by Theorem 4.2, $G$ is a subgraph of $G'$. Therefore, $G$ is a $(\varphi, t)$-supergraph of $G$. $\square$

We note that Lemma 6.1 alone does yield an algorithm to determine whether a graph $G$ has a $(\varphi, t)$-supergraph. If $G$ does not admit such a supergraph, then no $(t + 1)$-concrete tree decomposition $G$ belongs to $\mathcal{L}(\text{Sub}(A(\varphi, t + 1)))$. However, if $G$ does admit a $(\varphi, t)$-supergraph, then Theorem 4.3 only guarantees that some $(t + 1)$-concrete tree decomposition $T$ of $G$ belongs to $\text{Sub}(A(\varphi, t + 1))$. The problem is that $G$ may have infinitely many $(t + 1)$-concrete tree decompositions and we do not know a priori which of these should be tested for membership in $\mathcal{L}(\text{Sub}(A(\varphi, t + 1)))$.

The issue described above can be remedied with the results from Section 5. More specifically, from Theorem 5.5 we have that for any given connected graph $G$ of treewidth $t$ and maximum degree $\Delta$, one can construct a tree automaton $A(G, t + 1)$ over $B(t + 1)$ which accepts a $(t + 1)$-concrete tree decomposition $T$ if and only if the graph $G(T)$ is isomorphic to $G$. Note that $\mathcal{L}(A(G, t + 1))$ is an infinite language that contains $(t + 1)$-concrete tree decompositions of $G$ of all shapes and sizes. Therefore, a connected graph $G$ has a $(\varphi, t)$-supergraph if and only if

$$\mathcal{L}(A(G, t + 1)) \cap \mathcal{L}(\text{Sub}(A(\varphi, t + 1))) \neq \emptyset.$$  \hspace{1cm} (6.1)

The next theorem states that Equation 6.1 yields an efficient algorithm for testing whether connected graphs of bounded degree have a $(\varphi, t)$-supergraph.

Theorem 6.2 (Main Theorem). There is a computable function $f$, and an algorithm $A$ that takes as input a CMSO sentence $\varphi$, a positive integer $t$, and a connected graph $G$ of maximum degree $\Delta$, and determines in time $f(|\varphi|, t) \cdot 2^{O(\Delta t)} \cdot |G|^{O(t)}$ whether $G$ has a $(\varphi, t)$-supergraph.

Proof. By Lemma 6.1, $G$ has a $(\varphi, t)$-supergraph if and only if there exists some $T \in \mathcal{L}(\text{Sub}(A(\varphi, t + 1)))$ such that $T$ is a $(t + 1)$-concrete tree decomposition of $G$. By Theorem 5.5, $\mathcal{L}(A(G, t + 1))$ accepts a $(t + 1)$-tree decomposition of $G$ if and only if $G(T)$ is isomorphic to $G$. Therefore, $G$ has a $(\varphi, t)$-supergraph if and only if the intersection of $\mathcal{L}(A(G, t + 1))$ with $\mathcal{L}(\text{Sub}(A(\varphi, t + 1)))$ is nonempty.

By Theorem 5.5, the tree-automaton $A(G, t + 1)$ can be constructed in time $2^{O(\Delta t)} \cdot |G|^{O(t)}$, and therefore the size of $A(G, t + 1)$ is bounded by $2^{O(\Delta t)} \cdot |G|^{O(t)}$. By Theorem 4.3 and Theorem 3.3, the tree-automaton $\text{Sub}(A(\varphi, t + 1))$ can be constructed in time $f(|\varphi|, t)$ for some computable function $f : \mathbb{N}^2 \rightarrow \mathbb{N}$, and therefore, the size of $\text{Sub}(A(\varphi, t))$ is bounded by $f(|\varphi|, t)$.
Finally, given tree automata $\mathcal{A}_1$ and $\mathcal{A}_2$, one can determine whether $\mathcal{L}(\mathcal{A}_1) \cap \mathcal{L}(\mathcal{A}_2) \neq \emptyset$ in time $O(|\mathcal{A}_1| \cdot |\mathcal{A}_2|)$ (Lemma 2.1). In particular, one can determine whether

$$\mathcal{L}(\mathcal{A}(G, t + 1)) \cap \mathcal{L}(\text{Sub}(\mathcal{A}(\varphi, t + 1))) \neq \emptyset$$

in time $f(|\varphi|, t) \cdot 2^{O(\Delta \cdot t)} \cdot |G|^{O(t)}$.

\section{Contraction Closed Graph Parameters}

In this section we deal with simple graphs, i.e., graphs without loops or multiple edges. Therefore, we may write $\{u, v\}$ to denote an edge $e$ whose endpoints are $u$ and $v$. Additionally, whenever speaking of a property specified by an CMSO formula $\varphi$, we assume that $\varphi$ ensures that its models are simple graphs.

Let $G$ be a graph and $\{u, v\}$ be an edge of $G$. We let $G/uv$ denote the graph that is obtained from $G$ by deleting the edge $\{u, v\}$ and by merging vertices $u$ and $v$ into a single vertex $x_{uv}$. We say that $G/uv$ is obtained from $G$ by an edge-contraction. We say that a graph $G'$ is a contraction of $G$ if $G'$ is obtained from $G$ by a sequence of edge contractions. We say that $G'$ is a minor of $G$ if $G'$ is a contraction of some subgraph of $G$. We say that a graph $G$ is an apex graph if after deleting some vertex of $G$ the resulting graph is planar.

A graph parameter is a function $p$ mapping graphs to non-negative integers in such a way that $p(G) = p(G')$ whenever $G$ is isomorphic to $G'$. We say that $p$ is contraction closed if $p(G') \leq p(G)$ whenever $G'$ is a contraction of $G$.

A graph property is simply a set $\mathcal{P}$ of graphs. We say that a property $\mathcal{P}$ is contraction-closed if for every two graphs $G, G'$ for which $G'$ is a contraction of $G$, the fact that $G \in \mathcal{P}$ implies that $G' \in \mathcal{P}$.

\subsection{Diameter Improvement Problems}

Let $u$ and $v$ be vertices in an graph $G$. The distance from $u$ to $v$, denoted by $dist(u, v)$ is the number of edges in the shortest path from $u$ to $v$. If no such path exists, we set $dist(u, v) = \infty$. The diameter of $G$ is defined as $diam(G) = \max_{u,v} dist(u, v)$. In the PLANAR DIAMETER IMPROVEMENT problem (PDI), we are given an graph $G$ and a positive integer $d$, and the goal is to determine whether $G$ has a planar supergraph $G'$ of diameter at most $d$. As mentioned in the introduction, there is an algorithm that solves the PDI problem in time $f(d) \cdot |G|^{O(1)}$, where $f : \mathbb{N} \to \mathbb{N}$ is not known to be computable. Additionally, even the problem of determining whether PDI admits an algorithm running in time $f_1(d) \cdot |G|^{f_2(d)}$ for computable functions $f_1, f_2$ remains open for more than two decades [FL89, CGK+15]. The next theorem solves this problem when the input graphs are connected and have bounded degree.

\textbf{Theorem 7.1.} There is a computable function $f : \mathbb{N} \to \mathbb{N}$, and an algorithm $\mathcal{A}$ that takes as input, a positive integer $d$, and a connected graph $G$ of maximum degree $\Delta$, and determines in time $f(d) \cdot 2^{O(\Delta \cdot d)} \cdot |G|^{O(d)}$ whether $G$ has a planar supergraph $G'$ of diameter at most $d$.

\textbf{Proof.} It should be clear that there is an algorithm that takes a positive integer $d$ as input, and constructs, in time $O(d)$, a CMSO formula $\text{Diam}_d$ which is true on a graph $G'$ if and only if $G'$ has diameter at most $d$. Additionally, using Kuratowski’s theorem, and the fact that minor relation is CMSO expressible, one can define a CMSO formula $\text{Planar}$ which is true on a graph $G'$ if and only if $G'$ is planar. Finally, it can be shown that any planar graph of diameter at most $d$ has treewidth $O(d)$ (see Lemma 1 of [Epp00]). Therefore, by setting $\varphi = \text{Diam}_d \land \text{Planar}$, $t = O(d)$, and by renaming $f(|\varphi|, t)$ to $f(d)$ in Theorem 6.2,
we have an algorithm running in time \(f(d) \cdot 2^{O(\Delta d)} \cdot |G|^{O(d)}\) to determine whether \(G\) has a planar supergraph \(G'\) of diameter at most \(d\).

We note that the algorithm \(\mathfrak{A}\) of Theorem 7.1 does not impose any restriction on the degree of a prospective supergraph \(G'\) of \(G\). Theorem 7.1 can be generalized to the setting of graphs of constant genus as follows.

**Theorem 7.2.** There is a computable function \(f : \mathbb{N} \times \mathbb{N} \to \mathbb{N}\), and an algorithm \(\mathfrak{A}\) that takes as input, positive integers \(d, g\), and a connected graph \(G\) of maximum degree \(\Delta\), and determines in time \(f(d, g) \cdot 2^{O(\Delta d)} \cdot |G|^{O(dg)}\) whether \(G\) has a supergraph \(G'\) of genus at most \(g\) and diameter at most \(d\).

**Proof.** It can be shown that there is an explicit algorithm that takes a positive integer \(g\) as input and constructs a CMSO sentence \(\text{Genus}_g\) that is true on a graph \(G'\) if and only if \(G'\) has genus at most \(g\) [AGK08]. Additionally, it can be shown that graphs of genus \(g\) and diameter \(d\) have treewidth at most \(O(g \cdot d)\) [Epp00]. Therefore, by setting \(\varphi = \text{Genus}_g \wedge \text{Diam}_d\), \(t = O(g \cdot d)\), and by renaming \(f(\varphi, t)\) to \(f(g, d)\) in Theorem 6.2, we have that one can determine in time \(f(d, g) \cdot 2^{O(\Delta d)} \cdot |G|^{O(dg)}\) whether \(G\) has a supergraph \(G'\) of genus at most \(g\) and diameter at most \(d\).

A graph is 1-outerplanar if it can be embedded in the plane in such a way that every vertex lies in the outer face of the embedding. A graph is \(k\)-outerplanar if it can be embedded in the plane in such a way that after deleting all vertices in the outer face, the remaining graph is \((k - 1)\)-outerplanar. In [CGK+15] Cohen et al. have considered the \(k\)-OUTERPLANAR DIAMETER IMPROVEMENT problem \((k\text{-OPDI})\), a variant of the PDI problem in which the target supergraph is required to be \(k\)-outerplanar instead of planar. In particular, they have shown that the 1-OPDI problem can be solved in polynomial time. The complexity of the \(k\)-OPDI problem with respect to explicit algorithms was left as an open problem for \(k \geq 2\). The next theorem states that for each fixed \(k\), \(k\)-OPDI is strongly uniformly fixed parameter tractable with respect to the parameter \(d\) on connected graphs of bounded degree.

**Theorem 7.3.** There is a computable function \(f : \mathbb{N} \times \mathbb{N} \to \mathbb{N}\), and an algorithm \(\mathfrak{A}\) that takes as input, positive integers \(d, k\), and a connected graph \(G\) of maximum degree \(\Delta\), and determines in time \(f(k, d) \cdot 2^{O(\Delta k)} \cdot |G|^{O(k)}\) whether \(G\) has a \(k\)-outerplanar supergraph \(G'\) of diameter at most \(d\).

**Proof.** There is an algorithm that takes an integer \(k\) as input and constructs in time \(O(k)\) a CMSO sentence \(\text{Outer}_k\) that is true on a graph \(G\) if and only if \(G\) is \(k\)-outerplanar [JB15]. Additionally, it can be shown that \(k\)-outerplanar graphs have treewidth \(O(k)\). Therefore, by setting \(\varphi = \text{Outer}_k \wedge \text{Diam}_d\), and \(t = O(k)\) in Theorem 6.2, it follows that the problem of determining whether \(G\) has a \(k\)-outerplanar supergraph of diameter at most \(d\) can be decided in time \(f(k, d) \cdot 2^{O(\Delta k)} \cdot |G|^{O(k)}\) for some computable function \(f : \mathbb{N} \times \mathbb{N} \to \mathbb{N}\).

Finally, the SERIES-PARALLEL DIAMETER IMPROVEMENT problem (SPDI) consists in determining whether a graph \(G\) has a series parallel supergraph of diameter at most \(d\). The parameterized complexity of this problem was left as an open problem in [CGK+15]. The next theorem states that SPDI is strongly uniformly fixed parameter tractable with respect to the parameter \(d\) on connected graphs of bounded degree.

**Theorem 7.4.** There is a computable function \(f : \mathbb{N} \to \mathbb{N}\), and an algorithm \(\mathfrak{A}\) that takes as input, a positive integer \(d\) and a connected graph \(G\) of maximum degree \(\Delta\), and determines
in time $f(d) \cdot 2^{O(\Delta)} \cdot |G|^{O(1)}$ whether $G$ has a series-parallel supergraph $G'$ of diameter at most $d$.

**Proof.** There is a CMSO formula $SP$ which is true on a graph $G'$ if and only if $G'$ is series parallel. Additionally, series parallel graphs have treewidth at most 2. Therefore, by setting $\varphi = SP \land \text{Diam}_d$ and $t = O(1)$ in Theorem 6.2, it follows that the problem of determining whether $G$ has a series-parallel supergraph of diameter at most $d$ can be decided in time $f(d) \cdot 2^{O(\Delta)} \cdot |G|^{O(1)}$ for some computable function $f$. \qed

### 7.2. Contraction Bidimensional Parameters.

Fomin, Golovach and Thilikos [FGT11] have defined a sequence $\{\Gamma_k\}_{k \in \mathbb{N}}$ of graphs and have shown that these graphs serve as obstructions for small treewidth on $H$-minor free graphs, whenever $H$ is an apex graph. More precisely, they have proved the following result.

**Theorem 7.5** (Fomin-Golovach-Thilikos [FGT11]). For every apex graph $H$, there is a $c_H > 0$ such that every connected $H$-minor-free graph of treewidth at least $c_H \cdot k$ contains $\Gamma_k$ as a contraction.

We say that a graph parameter $p$ is Gamma-unbounded if there is a computable function $\alpha : \mathbb{N} \to \mathbb{N}$ such that $\alpha \in \omega(1)$, and $p(\Gamma_k) \geq \alpha(k)$ for every $k \in \mathbb{N}$.

We say that a parameter $p$ is effectively CMSO definable if there is a computable function $f : \mathbb{N} \to \mathbb{N}$, and an algorithm $A$ that takes as input a positive integer $k$ and constructs, in time at most $f(k)$, a CMSO-sentence $\varphi$ which is true on an graph $G$ if and only if $p(G) \leq k$. The following theorem is a corollary of Theorem 6.2 and Theorem 7.5.

**Theorem 7.6.** Let $p$ be a Gamma-unbounded effectively CMSO definable graph parameter, and let $P$ be a CMSO definable graph property excluding some apex graph $H$ as a minor. Then there is a computable function $f : \mathbb{N} \to \mathbb{N}$ and an algorithm $A$ that takes as input a positive integer $k$, and a connected graph $G$ of maximum degree $\Delta$, and determines, in time $f(k) \cdot 2^{O(\Delta \cdot f(k))} \cdot |G|^{f(k)}$, whether $G$ has a supergraph $G'$ such that $G' \in P$ and $p(G') \leq k$.

Note that similarly to the case of diameter improvement problem, if $p$ is an unbounded effectively CMSO definable graph parameter, then we can determine whether a graph $G$ has an $r$-outerplanar supergraph $G'$ with $p(G') \leq k$ in time $f(r, k) \cdot 2^{O(\Delta \cdot r)} \cdot |G|^{O(r)}$ for some computable function $f : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$. In other words, this problem, for connected bounded degree graphs, is strongly uniformly fixed parameter tractable with respect to the parameter $p$ for each fixed $r$.

**Definition 7.7.** A graph parameter $p$ is contraction-bidimensional if the following conditions are satisfied.

1. $p$ is contraction-closed.
2. If $G$ is a graph which has $\Gamma_k$ as a contraction, then $p(G) \geq \Omega(k^2)$.

For instance, the following parameters are contraction bidimensional.

1. Size of a vertex cover.
2. Size of a feedback vertex set.
3. Size of a minimum maximal matching.
4. Size of a dominating set.
5. Size of a edge dominating set.
(6) Size of a clique traversal set.

**Theorem 7.8** [FGT11, FLST10]. Let $p$ be a bidimensional parameter. Then if $p(G) \leq k$, the treewidth of $p$ is at most $O(\sqrt{k})$.

**Theorem 7.9.** For each effectively CMSO-definable contraction-bidimensional parameter $p$, there exists a computable function $f : \mathbb{N} \rightarrow \mathbb{N}$ and an algorithm $\mathcal{A}$ that takes as input a positive integer $k$, and a connected graph $G$ of maximum degree $\Delta$, and determines in time $f(k) \cdot 2^{O(\Delta \cdot \sqrt{k})} \cdot |G|^{O(\sqrt{k})}$ whether $G$ has a planar supergraph $G'$ with $p(G') \leq k$.

**Proof.** Since $p$ is effectively CMSO definable, there is some computable function $\alpha$ and an algorithm that take a positive integer $k$ as input and constructs in time $\alpha(k)$ a CMSO sentence $\varphi_p$ which is true on an graph $G$ if and only if $p(G) \leq k$. Additionally, by Theorem 7.8, if $p(G) \leq k$, then the treewidth of $G$ is bounded by $\sqrt{k}$. Therefore, by applying Theorem 6.2 with $\varphi = \varphi_p$, and $t = O(\sqrt{k})$, the theorem follows.

For instance, Theorem 7.9 states that for some computable function $f : \mathbb{N} \rightarrow \mathbb{N}$, one can determine in time $f(k) \cdot 2^{O(\Delta \cdot \sqrt{k})} \cdot |G|^{O(\sqrt{k})}$ whether $G$ has a planar supergraph $G'$ with feedback vertex set at most $k$. We note that in view of Theorem 7.8, the planarity requirement of Theorem 7.9 can be replaced for any CMSO definable property $\mathcal{P}$ which excludes some apex graph as a minor.

Appendix A. Proof of Theorem 3.3

Restatement of Theorem 3.3. There exists a computable function $f : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ such that for each CMSO sentence $\varphi$, and each $t \in \mathbb{N}$, one can construct in time $f(|\varphi|, t)$ a tree-automaton $A(\varphi, t)$ accepting the following tree language.

$$\mathcal{L}(A(\varphi, t)) = \{ T \in \text{Ter}(B(t)) \mid \mathcal{G}(B) \models \varphi \}.$$  \hfill (A.1)

Proof. Let $S$ and $S'$ be sets and let $R \subseteq S \times S'$ be a relation. For each element $s \in S$, we let $\text{Im}(R, s) = \{ s' : (s, s') \in R \}$ be the image of $s$ under $R$.

Let $X$ be a set of first-order variables and second-order variables and let $G$ be a graph. An interpretation of $X$ in $G$ is a function $\mathcal{J} : X \to (V \cup E) \cup (2^V \cup 2^E)$ that assigns a vertex $\mathcal{J}(x)$ to each first-order vertex-variable $x$, an edge $\mathcal{J}(y)$ to each first-order edge-variable $y$, a set of vertices $\mathcal{J}(X)$ to each second-order vertex-variable $X$, and a set of edges $\mathcal{J}(Y)$
to each second-order edge-variable $Y$. The semantics of a formula $\varphi$ with free variables $X$ being true on a graph $G$ under interpretation $J$ is the standard one.

Let $\mathcal{X}$ be a set of free first-order and second-order variables, and let $(B, b)$ be a $t$-concrete bag. An interpretation of $\mathcal{X}$ in $(B, b)$ is a relation $I \subseteq \mathcal{X} \times (B \cup \{b\})$ such that the following conditions are satisfied: $\text{Im}(I, x) \subseteq B$ and $|\text{Im}(I, x)| \leq 1$ for each first-order vertex-variable $x$; $\text{Im}(I, X) \subseteq B$ for each second-order vertex-variable $X$; $\text{Im}(I, y) \subseteq \{b\}$ for each first-order edge-variable $y$; and $\text{Im}(I, Y) \subseteq \{b\}$ for each second-order variable $Y$. We let $\mathcal{B}(t, \mathcal{X})$ be the set of all triples of the form $(B, b, I)$ where $(B, b)$ is a $t$-concrete bag and $I$ is an interpretation of $\mathcal{X}$ in $(B, b)$.

If $\mathcal{T}$ is a $t$-concrete decomposition in $\text{Ter}(\mathcal{B}(t))$, then an interpretation of $\mathcal{X}$ in $\mathcal{T}$ is a function $\mathcal{I} : \text{Pos}(\mathcal{T}) \to \mathcal{B}(t, \mathcal{X})$ where for each position $p \in \text{Pos}(\mathcal{T})$, $\mathcal{I}(p)$ is an interpretation of $\mathcal{X}$ in the $t$-concrete bag $\mathcal{T}[p]$, and for each first-order vertex-variable $x$ (edge-variable $y$), there is at most one position $p \in \text{Pos}(\mathcal{T})$ such that $|\text{Im}(I, x)| = 1$ ($|\text{Im}(I, y)| = 1$). If $\mathcal{I}$ is an interpretation of $\mathcal{X}$ in $\mathcal{T}$, then the interpretation of $\mathcal{X}$ in $\mathcal{G}(\mathcal{T})$ induced by $\mathcal{I}$ is the function

$$\mathcal{I} : \mathcal{X} \to (V_{\mathcal{G}(\mathcal{T})} \cup E_{\mathcal{G}(\mathcal{T})}) \cup (2^{V_{\mathcal{G}(\mathcal{T})}} \cup 2^{E_{\mathcal{G}(\mathcal{T})}})$$

defined as follows.

1. For each $s \in [t]$, each $s$-maximal component $P \subseteq \text{Pos}(\mathcal{T})$, and each first-order or second-order vertex-variable $x$, the vertex $v_{s_p}$ belongs to $\text{Im}(\mathcal{I}, x)$ if and only if there exists a position $p \in P$ such that $(x, s) \in \mathcal{I}(p)$.
2. For each $p \in \text{Pos}(\mathcal{T})$ such that $\mathcal{T}[p], b \neq \emptyset$, and each first-order or second-order edge-variable $y$, the edge $e_p$ belongs to $\text{Im}(\mathcal{I}, y)$ if and only if $(y, \mathcal{T}[p], b) \in \mathcal{I}(p)$.

If $\mathcal{T}$ is a $t$-concrete decomposition in $\text{Ter}(\mathcal{B}(t))$ and $\mathcal{I}$ is an interpretation of $\mathcal{X}$ in $\mathcal{T}$, then we write $\mathcal{T}^\mathcal{I}$ to denote the term in $\text{Ter}(\mathcal{B}(t, \mathcal{X}))$ where $\mathcal{T}^\mathcal{I}[p] = (\mathcal{T}[p], \mathcal{I}(p))$ for each position $p \in \text{Pos}(\mathcal{T})$. We say that $\mathcal{T}^\mathcal{I}$ is an interpreted term. We note that one can straightforwardly construct a tree automaton $\mathcal{A}(t, \mathcal{X})$ over the alphabet $\mathcal{B}(t, \mathcal{X})$ that accepts precisely the interpreted terms in $\text{Ter}(\mathcal{B}(t, \mathcal{X}))$.

For each CMSOformula $\psi$ with free variables $\mathcal{X}$ we will construct a tree-automaton $\mathcal{A}(\psi, t)$ over the alphabet $\mathcal{B}(t, \mathcal{X})$ whose language $\mathcal{L}(\mathcal{A}(\psi, t))$ consists of all interpreted terms $\mathcal{T}^\mathcal{I} \in \text{Ter}(\mathcal{B}(t, \mathcal{X}))$ such that $\mathcal{G}(\mathcal{T}) \models \psi$ under the interpretation $\mathcal{I}$ of $\mathcal{X}$ in $\mathcal{G}(\mathcal{T})$ induced by $\mathcal{I}$. The tree-automaton $\mathcal{A}(\psi, t)$ is constructed by induction on the structure of the formula $\psi$.

**Base Case.** In the base case, the formula $\psi$ is an atomic predicate. There are five cases to be considered. Below, we describe the behavior of the tree-automaton $\mathcal{A}(\psi, t)$ in each of these five cases. The proper specification of the set of states and set of transitions of each of the tree-automata described below is straightforward.

1. If $\psi \equiv (z_1 = z_2)$ where $z_1$ and $z_2$ are both vertex-variables, both edge-variables, both vertex-set variables or both edge-set variables, then $\mathcal{A}(\psi, t)$ accepts a term $\mathcal{T}^\mathcal{I}$ if and only if $\mathcal{T}^\mathcal{I}$ is an interpreted term, and for each position $p \in \text{Pos}(\mathcal{T})$, and each $s \in \mathcal{T}[p], B$, $(z_1, s) \in \mathcal{I}(p) \iff (z_2, s) \in \mathcal{I}(p)$.
2. If $\psi \equiv z \in Z$ where either $z$ is a vertex-variable and $Z$ is a vertex-set variable, or $z$ is an edge-variable and $Z$ is an edge-set variable, then $\mathcal{A}(\psi, t)$ accepts a term $\mathcal{T}^\mathcal{I}$ if and only if $\mathcal{T}^\mathcal{I}$ is an interpreted term and for each position $p \in \text{Pos}(\mathcal{T})$, and each element $r \in \mathcal{T}[p], B \cup \{\mathcal{T}[p], b\}$, $(z, r) \in \mathcal{I}(p) \iff (Z, r) \in \mathcal{I}(p)$. 
(3) If \( \psi \equiv \text{Inc}(y, x) \) where \( y \) is an edge variable and \( x \) is a vertex variable, then the automaton \( A(\psi, t) \) accepts a term \( T^Z \) if and only if \( T^Z \) is an interpreted term and there is some position \( p \in \text{Pos}(T) \) and some \( s \in T[p].B \) such that \( (x, s) \in \mathcal{I}(p) \), \( s \in T[p].b \), and \( (y, T[p], b) \in \mathcal{I}(p) \).

(4) If \( \psi \equiv \text{card}_{a, r}(Z) \) where \( 0 \leq a < r, r \geq 2 \), and \( Z \) is an edge-set variable, then the tree automaton \( A(\psi, t) \) accepts \( T^Z \) if and only if \( T^Z \) is an interpreted term, and the number of positions \( p \in \text{Pos}(T) \) such that \( T[p].b \neq \emptyset \) and \( (Z, T[p], b) \in \mathcal{I}(p) \) is equal to \( a \mod r \).

(5) If \( \psi \equiv \text{card}_{a, r}(Z) \) where \( 0 \leq a < r, r \geq 2 \), and \( Z \) is a vertex-set variable then the tree automaton \( A(\psi, t) \) accepts \( T^Z \) if and only if \( T^Z \) is an interpreted term and the number of pairs of the form \( (s, p) \in [t] \times \text{Pos}(T) \) such that \( s \in T[p].B \) and \( p \) is the root of \( P_{s, p} \) is equal to \( a \mod r \).

**Disjunction, conjunction and negation.** The three boolean operations \( \lor, \land, \neg \) are dealt with using the fact that tree-automata are effectively closed under union, intersection and complement (Lemma 2.1). Below, we let \( A(t, X) \) be the tree automaton generating the set of interpreted terms over \( B(t, X) \).

\[
A(\psi \lor \psi', t) = A(\psi, t) \cup A(\psi', t)
\]
\[
A(\psi \land \psi', t) = A(\psi, t) \cap A(\psi', t)
\]
\[
A(\neg \psi, t) = \overline{A(\psi, t)}
\]

Observe that in the definition of \( A(\neg \psi, t) \), the intersection with the tree-automaton \( A(t, X) \) guarantees that all terms in \( \mathcal{L}(A(\psi, t)) \) are interpreted.

**Existential Quantification.** Let \( I \) be an interpretation of \( X \) in \( B, b \), and let \( Z \) be either a first-order or a second-order variable in \( X \). We let \( I - Z = I \cap [(\forall Z) \times (B \cup \{b\})] \) be the relation obtained from \( I \) by deleting all pairs of the form \( (Z, r) \) for \( r \in B \cup \{b\} \).

To eliminate existential quantifiers we proceed as follows: For each variable \( Z \in X \), we let \( \text{Proj}_Z : B(t, X) \to B(t, X \setminus Z) \) be the map that sends each interpreted \( t \)-concrete bag \( (B, b, I) \in B(t, X) \) to the interpreted \( t \)-concrete bag \( (B, b, I - Z) \in B(t, X \setminus Z) \). Subsequently, we extend \( \text{Proj}_Z \) homomorphically to terms by setting \( \text{Proj}_Z(T)[p] = \text{Proj}_Z(T[p]) \) for each position \( p \) in \( \text{Pos}(T) \). Finally, we extend \( \text{Proj}_Z \) to tree languages over \( B(t, X) \) by applying this map to each term of the language. Then we set

\[
A(\exists Z \psi(Z), t) = \text{Proj}_Z(A(\psi(Z), t)).
\]

We note that if \( \psi \) is a sentence, i.e., a formula without free variables, then by the end of this inductive process all variables occurring in \( \psi \) will have been eliminated. In this way, the language \( \mathcal{L}(A(\psi, t)) \) will consist precisely of the interpreted decompositions \( T^e \in \text{Ter}(B(t, \emptyset)) \) where \( \varepsilon \) is the empty interpretation, that assigns \( \varepsilon(p) = \emptyset \) for each \( p \in \text{Pos}(T) \), and \( T \models \psi \). Now consider the map that \( m : B(t, \emptyset) \to B(t) \) that sends each triple \( (B, b, \emptyset) \in B(t, \emptyset) \) to the \( t \)-concrete bag \( (B, b) \). Then, by setting \( A(\psi, t) \leftarrow m(A(\psi, t)) \), we have that \( A(\psi, t) \) accepts a term \( T \in B(t) \) if and only if \( T \) is a \( t \)-concrete tree decomposition such that \( T \models \varphi \). \( \square \)
